Serious yield losses occurred especially in areas where tomatoes are produced for 11-12 months of the year. Insecticides registered against other tomato pests were not effective because leafminer is resistant to most insecticides. The insect growth regulator cyromazine was registered in 1986 by Ciba-Geigy South Africa for leafminer control. In 1991 complaints were received of poor leafminer control in Mooketsi. Resistance of local leafminer populations was suspected. This article reports on the cyromazine susceptibility/resistance of some leafminer populations from Mooketsi and from other areas which were tested in the laboratory. Data was collected over a two-year period. A spray programme for tomatoes against leafminer resistance management was also introduced after the first data was collected. This data was compared to the second year's data, to compare the levels of resistance.

Ciba-Geigy South Africa and the Agricultural Research Council's, Roodeplaat Vegetable and Ornamental Plant Institute, was involved in this research.

19-101

PRO-ACTIVE RESISTANCE MONITORING PROGRAMS FOR AVERMECTIN INSECTICIDES IN CROP PROTECTION

R. K. Jansson, D. Rugg, R. A. Dybas
Agricultural Research and Development, Merck Research Laboratories, Merck & Co., Inc., P.O. Box 450, Hillsborough Road, Three Bridges, NJ 08887

The avermectin insecticides (abamectin and emamectin) have an unprecedented potency to arthropod pests. LC90 values range between 0.001-0.2 ppm for most pests for which control is claimed. Pro-active monitoring for resistance to the avermectin insecticides has been conducted for several years. Currently, resistance monitoring programs are focused on those pests considered to be most problematic with regard to development of resistance to insecticides. These pests include twospotted spider mite (*Tetranychus urticae* Koch), leafminer (*Liriomyza trifolii* (Burgess)), Colorado potato beetle (*Leptinotarsa decemlineata* (Say)), and diamondback moth (*Plutella xylostella* (L.)). We are also monitoring for resistance to abamectin in citrus rust mite (*Phyllocoptruta oleivora* (Ashmead)). Marked differences (> 100-fold) in twospotted spider mite susceptibility to abamectin have been observed among populations. The highest levels of resistance occur on glasshouse-grown ornamentals that are subjected to intense selection pressure. However, practical resistance (i.e., field failure) has not been observed to date. In leafminers and Colorado potato beetle, extensive monitoring has found up to 16- and 15-fold differences in susceptibility to abamectin, respectively. In diamondback moth, up to 4- and 100-fold differences in susceptibility to emamectin and abamectin, respectively, were found. A review of each of these monitoring programs will be presented. The importance of pro-active resistance monitoring in resistance management programs will be highlighted.

19-100

COMBATING RESISTANCE TO IMIDACLOPRID IN WHITEFLIES BY VARIOUS PREVENTIVE STRATEGIES (HOMOPTERA: ALEYRODIDAE)
N. Prabhaker, S. J. Castle¹, N. Toscano² and T. J. Henneberry³

Department of Entomology, University of California, Riverside, CA - 1 USDA, ARS, Irrigated Desert Research Station, Brawley, CA - 2 Department of Entomology, UC Riverside - 3 USDA, ARS, Western Cotton Research Laboratory, Phoenix, AZ, USA

One of the most encouraging developments in whitefly management in Imperial Valley, CA, has been the introduction of imidacloprid-formulated insecticides. Imidacloprid provides season-long control in fall vegetables and spring melons, and requires fewer treatments than with spray insecticides. This compound represents a valuable new tool in insect pest management, and as such should be safeguarded from debilitation through largescale resistance development. Therefore, resistance management programs are essential for prolonging the life of imidacloprid under field conditions. Towards this goal, we are evaluating restriction of imidacloprid treatments, alternation of imidacloprid with insecticides having different modes of action to delay resistance and the effect of immigration of susceptible individuals.

A resistant strain of *Bemisia tabaci* was established by selection with imidacloprid for approximately two years. The stability of imidacloprid resistance in this strain is under evaluation using a rotation regimen of different chemistries and also by withdrawal of imidacloprid selection. Five subsets of this resistant colony were subjected to selection with imidacloprid, bifenthrin, chlorpyrifos, amitraz and buprofezin on a continuous and rotational sequence. A sixth subset of the resistant strain was maintained with no selection. Susceptibility to imidacloprid was monitored using a hydroponic bioassay developed in this laboratory. Resistance to imidacloprid remained high with continuous selection (RR= 60-fold). Lower levels of resistance to imidacloprid were observed in whiteflies subjected to a rotation regimen with different insecticides. Resistance to imidacloprid was slow to decline initially in the absence of selection but declined considerably after a few generations. Our study indicates that resistance to imidacloprid declines when treatments are withdrawn. Additionally, resistance can be delayed under a rotational scheme in combination with different chemistries, thus prolonging the effectiveness of imidacloprid.

19-102

INSECT RESISTANCE- INDUSTRY IN PARTNERSHIP THROUGH IRAC

S. Irving, DuPont de Nemours, European Research and Development Center, 68740 Nambesheim, France.

H. Buholzer, Ciba-Geigy Ltd., Crop Protection Division, 4002 Basal, Switzerland.

Insect resistance to insecticides is a well documented and growing problem. In an age of environmental consciousness, the decreasing number of insecticides available for use constantly reduces the available options. This and the restricted number of different modes of action available requires all involved in agriculture and pest control to preserve our present weapons in the battle against insect and mite pests.

The importance of resistance is widely perceived, with input from regulators, academics, officials and farmers. Getting effective means of combating resistance is in everyone's interest and requires clear communication between all parties. Only in this way can we achieve sustainable pest control. The paper discusses practical examples of the problem, what industry (as IRAC) is doing and assesses the future collaborations which will be required to achieve this objective.

19-103

INSECTICIDE RESISTANCE DYNAMICS IN
Helicoverpa armigera (HUB) IN EASTERN U.P.
(INDIA)

H.N.Singh, S.J. Jose Rose and H.K.Singh
Deptt. of Entomology & Agril. Zoology, I.A.Sc.
Banaras Hindu University, Varanasi (India)

Discriminatory dose testing in 30-40 mg larvae of *H. armigera* from six locations within 70 km radius from Varanasi against cypermethrin, endosulfan, quinalphos and fenvalerate exhibited high resistance not referable to location, cropping system, and insecticide input. Regular fortnightly observations from Varanasi showed highest resistance in Oct population influx on early pigeonpea after two months of absence. A less severe resistance peak was exhibited during Feb-April. Both the peaks diluted drastically in successive months. No change of mixed function oxidase, acetylcholinesterase and carboxylesterase activity and host plants on resistance and also the fact that resistance level corrected with growth rate, suggested this phenomenon to be due to vigour tolerance. Draustic reduction of resistance in inbred population during F1 and F2, followed by nonviable egg laying during F4 and F5 and lack of genetic nature suggested this resistance to be of acquired origin. Perhaps the resistance in this innocent region is brought from distant focal areas with intense insecticide use through migration/dispersal.. This gets diluted to the level of completely susceptible population in July and August every year most of which perishes out of self sterility supporting migration.

19-105

RESISTANCE TO AZINPHOSMETHYL IN CODLING
MOTH: PATTERNS AND MANAGEMENT POTENTIAL

S. C. Welter and J. Dunley

Department of Environmental Science, Policy, and Management,
University of California, Berkeley, CA, USA - 1 Department of
Entomology, Washington State University, Pullman, WA USA
Low levels of resistance to azinphosmethyl were discovered in
populations of codling moth in 1989 in California. More recent
surveys have detected 4-15 fold levels of resistance in additional
sites and counties in California. While azinphosmethyl resistance
is still at levels that do not confer field failures, growers in areas
with resistance experience difficulty controlling codling moth,
resulting in increased Guthion use. Whereas multiple
mechanisms of resistance are suspected, resistance to
azinphosmethyl has been correlated with other organophosphates,
carbamates, pyrethroids (e.g. esfenvalerate), and one insect
growth regulator. Negatively correlated cross resistance also has
been observed with chlorpyrifos and methyl parathion.
Pheromone mating disruption was initiated on a regional basis in
1993 over 308 ha of Bartlett pears as a resistance management
tool to take advantage of the high fitness cost associated with
azinphosmethyl resistance in codling moth. In 1994, initial
surveys suggested a 20% decline in mean resistance levels for the
region after 2 years of mating disruption. However, in 1995, this
pattern was reversed apparently by single widespread application
of azinphosmethyl to the project.

19-104

SUBLETHAL DOSAGES OF SOME INSECTICIDES: AN
IMPROVEMENT TO THE EFFICACY OF BIOINSECTICIDES

R. Dobrinčić, J. Igrc-Barčić

Department of Zoology, Agricultural faculty, Zagreb, Croatia

Bioinsecticides based on *Bacillus thuringiensis* have a slow initial action and their efficacy very rarely reaches the degree of the efficacy of chemical insecticides. At the Agricultural faculty at Zagreb first trials to improve these deficiencies started Kovačević as early as 1958 and were continued later by other scientists (Maceljski, 1974 etc.). In the last years we tried to investigate the possibility to include the use of sublethal dosages of chemicals in the Colorado potato beetle (CPB) resistance management, because the problem of resistance of this insect to OP, OC and P insecticides is very acute in Croatia. We expected to improve the control of the CPB by using ecologically safer control methods.

By sublethal dosage we consider dosages lower than 10% of the normal dosage. Low dosages consisting from 10--50% of the recommended dosage we consider as subnormal dosages.

In our two years trials with larvae of the CPB sublethal dosages of some OP (chlorpyrifos) and P (alphacypermethrin, lambda-cyhalothrin and a combination of chlorpyrifos and cypermethrin) insecticides so as one IGR (hexaflumuron) were added to Novodor, an insecticide based on B.t. tenebrionis. The trials were conducted by using the IRAC 7 method. To the recommended dosage of Novodor, dosages containing 1-10% of the recommended dosage of the previously mentioned insecticides were added.

In most cases between the components used in trials an independent synergism was established. Some cases of antagonism were established also. The results of these trials shows a good possibilities to improve the action of the B.t. bioinsecticide by using sublethal dosage, but will be continued by including dosages of chemicals lower than 1% of the recommended dosage.

19-106

PRESENT INSECTICIDE USE PRACTICES ON COLE CROPS
IN PUNJAB (INDIA) AND STRATEGIES FOR MANAGING
MULTIPLE INSECTICIDE RESISTANCE IN DIAMONDBACK
MOTH

B. S. Jola, R. P. Chawla and A. S. Udeaan
Department of Entomology, Punjab Agricultural
University, Ludhiana, India

The indiscriminate and intensive use of insecticides for producing bluish free heads of cole crops has resulted in emergence of multiple resistance in Diamondback moth to currently available major groups of insecticides. Cross-resistance investigations have revealed some highly promising alternate insecticides and bioinsecticides with entirely different mode of action like Cartap hydrochloride, diafenthiuron, flufenoxuron and B.t. Integration of these products with conventional insecticides by their sequential and or combined use for managing the pest population below the threshold levels so as to delay the onset of resistance would require field scale evaluation. The strategy thus formulated would take into consideration the commercial quality criteria of the grower achievable by sustained curbing of the build up of the pest population without accompanying residue hazards.

19-107

THE STRUGGLE WITH LARVAE OF BLOOD-SUCKING MOSQUITOS BY THE METHOD OF INSECTICIDES AND REGULATORS OF INSECT DEVELOPMENT (RID) INSERTION IN TURNS INTO NATURAL RESERVOIRS

M. Kostina

Laboratory of Arthropods Control System Development, Scientific Research Institute for Preventive Toxicology and Desinfection, Moscow, Russia

Resistance rise for two agents, effected on different stages of insect development, is less probable than for intensive applied single one. So we have developed the rotary schemes for the preparations related to RID group - juvenile hormone analogues (JHA) and chitine synthesis inhibitors (CSI) and to the groups of phosphorous organics (POC), pyretroides and bacterial insecticide preparations. The rotary schemes were formed on the strength of the resistance rise mechanisms: JHA - pyretroides; CSI - POC; CSI(JHA) - bacterial preparations. Prolongated effect (equal to 1,4-2 times for POC and 1,3-1,6 times for pyretroides and bacterial preparations) is achieved if these preparations are inserted after JHA or CSI and not on the contrary, since the combination "insecticide - JHA (CSI)" had an ordinary effect. The term of the second agent insertion is a crucial factor for the effect prolongation. This regularity was corroborated during 5 years at the 182 reservoirs at aride and temperate zones. Insertion of preparations "JHA (CSI) - insecticide" in indicated turns results in 1,5-2 times expense quota decreasing with preservation of effectiveness; that leads to reduction of the number of preparation insertions into environment and so to decreasing of ecologic load per hectare.

19-108

EXPLORING PLANT PRODUCTS POTENTIAL FOR THE MANAGEMENT OF INSECTICIDE RESISTANCE OF *HELICOVERPA ARMIGERA* IN COTTON IN INDIAGavi Gowda¹, A.Regupathy², N.J.Armes³

1,2 Department of Entomology, Tamil Nadu Agricultural University, Coimbatore-641 003, India. 3.Natural Resources Institute, Chatham Maritime, Kent, U.K.

Regular monitoring of field populations since 1993-94 revealed that resistance both to fenvalerate and cypermethrin was very high in all monitoring regions with situations being most severe (more than 80% survival) at fenvalerate 0.2 µg and cypermethrin 0.1 µg discriminating doses. Studies were conducted to optimize pest management components with a view to developing and insecticide resistance management (IRM) strategy for cotton in India.

Application of neem oil based formulation viz., Nimbecidine 0.03% EC and TNAU Neem 0.03% EC effected 45-70% reduction of leaf hoppers, *Amrasca biguttula biguttula* Ishida and 30-60% by reduction of cotton aphid, *Aphis gossypii* G.

Application of neem seed kernal extract (NSKE) 5%, neem leaf extract (NLE) 5%, *Vitex negundo* leaf extract (VLE) 5%, *Ipomoea* leaf extract (ILE) 5% and Pongamia oil 80 EC (PO 80 EC) at 0.2 and 0.4 % reduced egg laying by 53.6%, 52.6%, 27.8%, 4.0%, 37.5% and 69.0% respectively. Among the various oils, (sesamum, cotton, sunflower, palm, niger, custard apple, castor, neem citronella and pongamia) evaluated pongamia oil synergised well with fenvalerate and cypermethrin. The suppression of fenvalerate and cypermethrin resistance was to the extent of 80% and 59.6, respectively. The level of suppression was comparable with the effect of piperonyl butoxide, the mixed function oxidase inhibitor synergist. Other oils did not show any significant synergistic effect.

The potential of Nimbecidine 0.03% EC and TNAU Neem oil 0.03% to formulations for checking early season pests and NSKE, NLE, VLE, PO 80 EC as a practically realizable synergist for fenvalerate and cypermethrin for *H.armigera* is discussed.

19-109

INSECTICIDE RESISTANCE AND THE EC AUTHORISATION REQUIREMENTS

C. FURK

Pesticides Safety Directorate, York, UK

ABSTRACT

Provision of information on resistance is a requirement of the pesticide registration process in the European Union (EU). An outline of how these requirements relate to insecticide resistance is provided in this paper.

Entomophagous Insects and Biological Control

20-001

GLOBAL APPLICATIONS AND REQUIREMENTS FOR ARTIFICIALLY REARED PARASITOIDS AND PREDATORS
N. C. Leppla

United States Department of Agriculture, Animal and Plant Health Inspection Service, National Biological Control Institute, Riverdale, MD USA

The use of insect parasitoids and predators in augmentative biological control is currently limited by cost of production, storage and handling techniques, standards and procedures for measuring success, efficacy data on levels of parasitization and crop protection, regulatory requirements for permits and "labels," creative strategies for their use, and resources dedicated to research and technology transfer. Ongoing basic and applied research is overcoming many of these limitations by developing *in vitro* rearing techniques and conducting related field evaluations. This work is focused on insect parasitoids and predators, and associated cropping systems that represent promising biological control systems.

20-002

INSECT-FREE DIET TESTED FOR REARING *PERILLUS BIOCULATUS*, *PODISUS MACULIVENTRIS* AND *COLEOMEGILLA MACULATA*.

T. A. Coudron, P. D. Greany¹

USDA ARS Biological Control of Insects Research Laboratory, Columbia, MO USA -
¹ USDA ARS Insect Attractants, Behavior and Basic Biology Research Laboratory, Gainesville, FL USA.

The objective of this study was to evaluate the nutritional viability of a single empirical medium for several species of entomophages. Two pentatomids and one coccinellid were tested since an empirically based medium may prove more complete for predaceous entomophages, due to their reliance on extra-oral digestion to enhance the nutrient quality of their food source. Gel and liquid forms of the medium were used as well as rearing chambers constructed of different materials.

Newly emerged adults of *Podisus maculiventris* (Hemiptera: Pentatomidae) fed on the liquid form of the medium, laid viable eggs, and the F₁ generation developed through to adults when reared on the liquid medium, but eggs of the F₁ adults were not viable. Adults of *Perillus bioculatus* (Hemiptera: Pentatomidae), that were converted from a larval-lepidopteran diet to the liquid medium, oviposited, the eggs hatched, and the F₁ nymphs developed when reared on the liquid medium, to adults that oviposited but none of the eggs were viable. Larvae and adults of *Coleomegilla maculata* (Coleoptera: Coccinellidae) fed best on a gelled version of the medium. Only late instar larvae were tested, and they did develop through to the adult stage. The development of all three predators was slower on the empirical medium than on an insect-based diet. Seasonal variations (e.g. summer vs. winter), medium delivery system, and chamber composition (e.g. paper vs. plastic) may impact the observed rate of development. Although limitations are evident with this insect-free empirical medium, it may have the potential of serving as a starting medium for predaceous entomophages.

20-003

ARTIFICIAL DIETS FOR REARING A PREDACIOUS COCCINELLID *MENOCHILUS SEXMACULATUS* FABRICIUS

M.Y. Hussein

Department of Plant Protection, Universiti Pertanian Malaysia, 43400 Serdang, Selangor, MALAYSIA

Menochilus sexmaculatus is the most common and intensively studied species of coccinellid predator in Malaysia. Currently the larva and adult predators can be successfully reared on aphids of various species. However, rearing the predators using artificial diets has only been attempted recently. A diet consists of chicken liver, yeast and sucrose has been formulated, tested and found suitable for rearing larvae and adult predators. Adult predators (males and females) seemed to live longer when fed on artificial diets as compared to diets of aphids (*Aphis craccivora*). Similarly, more eggs were obtained from female coccinellids fed on artificial diets. However, the larval predators showed slower rate of growth resulting in lighter pupae and smaller size adults when compared to those fed on aphids. Diet formulation seemed quite critical in determining diet acceptance especially by larvae. While the adult predators can easily accept dry, powdered formulation but the larvae will only feed on slightly moist formulation. Egg hatchability was high (70-80%) for both diet regimes. The inclusion of chicken liver is critical as it is a good source of protein which is vital for egg production. Research is now underway to encapsulate the liquid form of the diet using paraffin-wax combination.

20-004

THE INFLUENCE OF DIETARY PROTEIN HYDROLYSATES ON THE REPRODUCTION OF CERTAIN CHRYSOPIDS AND COCCINELLIDS

K. S. Hagen
Center for Biological Control, University of California,
Berkeley, USA

Protein hydrolysates of yeasts (produced by autolysis and/or by adding proteolytic enzymes) either mixed or provided separately with sugars form suitable adult diets for inducing good egg production in many insects that feed on honeydews, nectars, or pollens. Partially hydrolyzed protein is superior to both unhydrolyzed and completely hydrolyzed proteins. For *Chrysoperla* spp. (*carnea* complex), a ratio of one part protein hydrolysate to two parts sugar is effective, but for predaceous species, e.g. *Chrysopa* spp. (*nigricornis*), *Harmonia* spp., *Olla* sp. and overwintered *Hippodamia convergens*, this ratio should be at least one to one. Predaceous adult diets should also contain cholesterol (egg yolk) ascorbic acid and tocopherol. Water is provided separately.

When protein hydrolysates of lactalbumin and/or casein are used, a ratio of one to one should be followed. B-complex vitamins must be added (which can be provided with yeast powder) along with egg yolk, ascorbic acid, and tocopherol. If casein hydrolysate is used without other proteins, cystine should be added.

20-006

PREDACEOUS PENTATOMIDS ON ARTIFICIAL NUTRITIONAL DIETS: ENZYMOLOGICAL ASPECTS

I. G. Yazlovetsky, V. V. Sumenkova, E. M. Moontyan
Institute of Biological Plant Protection
Moldavian Academy of Sciences, Kishinev, Moldova

To our opinion, difficulties of predaceous *Pentatomidae* rearing *in vitro* are conditioned by specific peculiarities of feeding and digestion mechanisms of this group of insects. To reveal the above mentioned peculiarities we study localization, composition and properties of the main digestive enzymes of *Podisus maculiventris* (Say) and *Perillus bioculatus* (Fabr.) (Hemiptera: *Pentatomidae*) larvae. Activity of proteolytic and amylolytic enzymes under the absence of that of lipase was found in salivary glands of both species. Conclusion was made on the importance of non - midgut digestion of protein and carbohydrate food components as an unlikely mechanism of non - midgut digestion of fat by predaceous *Pentatomidae* larvae. It was established that digestive proteases of *P. maculiventris* and *P. bioculatus* as that of the majority of other bugs, are represented mainly by cathepsin-B-like enzymes, which differs them from many other insects using trypsin-like proteases for digestion of proteins. It results in the necessity of careful selection of protein components for artificial nutritional diets for predaceous *Pentatomidae* according to hydrolysing ability of cathepsin-B-like enzymes from their alimentary canal.

20-005

EXTRA-CELLULAR MATRICES: WHAT ROLE FOR ENTOMOPHAGOUS INSECTS IN ARTIFICIAL DIETS?

Allen Carson Cohen and Donald Brummett
Western Cotton Research Laboratory, USDA, ARS,
4135 E. Broadway Rd., Phoenix, AZ 85040.

Most predators and probably parasites ingest their prey (or hosts) as liquids. However, the tissues of the prey are composed of cells that are held together by a complex matrix composed of collagen, elastin, glycosaminoglycans (GAGs), including hyaluronic acid, chondroitin sulfate and heparin as well as cell membrane-connected proteins. This complex, which gives tissues structure and stability, is a barrier to diffusion of digestive enzymes; and it may also be a source of nutrients to the entomophage. Some predators have special digestive enzymes, such as elastases, that attack some components of the inter-cellular matrix, helping to liquefy the prey's contents. Questions are raised here as to the possibility that such a matrix is desirable in artificial diets for predators.

20-007

IN VITRO REARING OF *EUCELATORIA BRYANI* SAB. AND *EXORISTA LARVARUM* (L.) (DIPTERA: TACHINIDAE)

A. Bratti - Dipartimento di Biologia, Sezione di Botanica,
Università degli Studi di Ferrara, Corso Porta Mare, 2 - 44100
Ferrara - Italia

Eucelatoria bryani Sab. and *Exorista larvarum* (L.) are two parasitoids that attack important pest in agriculture. *In vitro* rearing system of *E. bryani* was made more economical reducing free aminoacids by half and adding yeast powder at varying concentrations. Tissue culture media added with insect components were used in order to improve the flies size.

E. larvarum was reared on meridic diets based on two tissue culture media (TNM-FH, SCHNEIDER'S), egg yolk, bovine serum, wheat germ and yeast without insect components. An average of about 20% of the eggs regularly failed to hatch. The adult yield reached was around 50% and the puparia average weight values were higher than 60 mg.

20-008

POSSIBILITIES OF MASS PRODUCTION OF THE PARASITOID *EXORISTA LARVARUM* (L.) (DIPTERA: TACHINIDAE) ON OLIGIDIC DIETS

E. Mellini, G. Campadelli, M.L. Dindo

Istituto di Entomologia "Guido Grandi", Università degli Studi di Bologna, Italy

Attempts have been made by our research group to rear *in vitro* 4 tachinid species. Successful results, such as to permit the mass production in artificial media, however, have so far been obtained only for *Exorista larvarum*, a gregarious larval parasitoid of many Lepidoptera. Ease of rearing *E. larvarum in vitro* may be related to the simple relationship between this parasitoid, which is an idiobiont, and its host. Since larvae induce primary integumental respiratory funnels, they may display similar behaviour in the host and in the gelled diet.

Testing was mainly carried out using oligidic diets. The complete development of *E. larvarum* was obtained on different media, the simplest one containing distilled water, yeast extract, chicken egg yolk and saccharose. Rearing techniques were progressively simplified. In particular, plastic multi-well plates, that were originally used as rearing containers, were replaced with glass Petri dishes, in which the larvae can be cultured gregariously, instead of separately.

In the most suitable media, the percentage yields of adults, based on the number of eggs placed on the diet, were similar to those usually obtained in the factitious host *Galleria mellonella* L. (≈50%). In the laboratory, adults obtained *in vitro* mated, parasitized *G. mellonella* larvae, and produced a normal second generation.

When the above diet was integrated with 5% homogenate of *G. mellonella* larvae, the puparia weighed considerably more than those usually obtained *in vivo*. For this reason, as well as to secure a sort of "biochemical bridge" between the two symbionts, we think that it may be better not to completely eliminate host material from the artificial medium. At the moment, however, the host has to be necessarily reared in order to obtain *E. larvarum* macrotype eggs to be transferred onto the diet. In fact, oviposition by the adult onto artificial substrates has not yet been obtained.

20-010

IN VITRO REARING OF HOUSE FLY PARASITOIDS (HYMENOPTERA: PTEROMALIDAE)

P. Fanti¹, S.B. Vinson

Department of Entomology, Texas A&M University, College Station, TX USA

-1 Present address: Dipartimento di Biologia, Difesa e Biotecnologie Agro-Forestali, Università della Basilicata, Potenza, Italy.

In vitro rearing of pteromalid wasps (*Muscidifurax zaraptor*, *Spalangia endius*, *Nasonia vitripennis*), pupal ectoparasitoids of *Musca domestica* and other filth flies, was successful utilizing several diets, with or without insect components.

The three species developed from egg to the adult on media containing insect material, extracted from pupae of either the natural host or the non-host species, *Heliothis virescens*.

M. zaraptor and *S. endius* attained the adult stage also on diets containing an amount of pupal extract as low as 5% (v/v). Further, *M. zaraptor* completed their development on diets devoid of insect components, though at lower rates.

The adult parasitoids reared *in vitro* successfully oviposited on host pupae, producing viable offspring.

While in nature *M. zaraptor* is a solitary parasitoid, several larvae successfully developed and reached the adult stage *in vitro* in the same well.

The results suggest that, at least for *M. zaraptor*, no special "host factors" are necessary to support larval growth.

20-009

IN VITRO REARING OF PARASITOIDS

S. Yagi¹, H. Shinbo², S. Nakamura

International Centre of Insect Physiology and Ecology, P.O. Box 30772, Nairobi, Kenya

-1 Japan International Research Center for Agricultural Sciences, Ohwashi, Tsukuba, Japan

-2 National Institute of Sericultural and Entomological Science, Ohwashi, Tsukuba, Japan

In vitro rearing of a parasitoid wasp and a fly by artificial diets is reviewed for research on physiology of their growth and development. A gregarious larval parasitoid wasp, *Cotesia kariyai*, was reared *in vitro* by insect tissue culture media containing silkworm haemolymph (BMH). After 4 days culture, the eggs hatched to 1st instar larvae released with hundreds of teratocytes. Both the larvae and teratocytes greatly increased their volume and maintained for at least 2 weeks.

A tachinid parasitoid fly, *Exorista japonica*, can be reared *in vitro* from eggs to adults by artificial diets. Added absorbent cotton immersed in each culture well caused to increase formation of the respiratory funnels in the 1st instar larvae soon after hatching. BMH with the cotton was the best diet for obtaining about 20% of adult flies.

20-011

IN VITRO REARING OF *APHIDIUS ERVI* HALIDAY (HYMENOPTERA, BRACONIDAE)M. C. Digilio, F. Pennacchio¹, P. Fanti¹, E. TremblayDipartimento di Entomologia e Zoologia Agraria, Università di Napoli "Federico II", Portici (NA), Italy - ¹Dipartimento di Biologia, Difesa e Biotecnologie Agro-Forestali, Università della Basilicata, Potenza, Italy

Aphidius ervi Haliday is an endophagous larval parasitoid of aphids, with a rather broad host range, which includes several species of economic importance. *In vitro* rearing of this parasitoid species has been attempted. A simple artificial diet devoid of insect material has been developed by adding to the cell culture medium IPL-41 the following ingredients: fetal bovine serum, bovine albumin and chicken egg yolk. The addition of this latter component stimulated the larval growth from mature embryo to last instar. However, while larval size and developmental time of 1st instars are similar to those registered *in vivo*, 2nd instars and mature larvae showed a reduced growth. Based on *in vivo* physiological studies (Pennacchio *et al.*, 1995, Arch. Insect Biochem. Physiol., 30, 351-367), selected host-derived components are being tested *in vitro* to assess their nutritional value. The oviposition behaviour has also been considered. Physical cues play a fundamental role in eliciting parasitoid oviposition. In fact, a specific artificial colour applied to aphid dummies can stimulate an ovipositional response in 95% of tested females. This information is being used to develop a technical device to obtain parasitoid oviposition on artificial substrates.

20-012

GROWTH AND DEVELOPMENT OF THE ENDOPARASITOID *MICROPLITIS CROCEIPES* (BRACONIDAE) IN VITRO AND ON FACTITIOUS HOSTS

S. Ferkovich, Prem Gupta, C. Dillard, H. Oberlander and D. Blumberg¹
Insect Attractants, Behavior, Basic Biology Research Laboratory, Agriculture Research Service, U. S. Department of Agriculture, Gainesville, Florida, 32604. ¹Department of Entomology, Agricultural Research Organization, The Volcani Center, Bet Dagan, Israel

Newly laid eggs of *Microplitis croceipes* must be exposed to components normally encountered in host hemolymph to initiate development. This requirement was met by incubating pre-germ band eggs of *M. croceipes* in IPL-52B, Grace's, and ExCell 400 media preconditioned for 24 hrs with five lepidopteran cell lines derived from fat body (IPLB-LdFB), imaginal wing discs (IAL-TND1, IAL-SFD1), or pupal ovaries (BCIRL-HZ-AMN1, BCIRL-HV). Egg development was dependent upon the composition of the medium, and the species and tissue type of the cell line source. The two imaginal disc cell lines and the fat body cell line were most effective in promoting germ band formation; whereas, the fat body cell line and the *T. Ni* imaginal wing disc-derived line were the most effective in promoting hatch. Because eggs developed only to the first instar in vitro, we examined the potential of rearing the parasitoid on six atypical hosts that are less expensive to rear than the natural host. Acceptance of hosts for oviposition by *M. croceipes* was accomplished by treating the larvae with frass plus hemolymph from *H. zea* larvae. Only *Galleria mellonella* and *Spodoptera frugiperda* allowed development of the parasitoid to the adult stage; however, the size of the resultant adult parasitoids was smaller and the numbers produced were lower than those parasitoids reared on *H. zea*. Efforts to reduce encapsulation of the parasitoid by treating the host larvae with gamma radiation, extreme temperatures, and phenylthiourea and supplementing the host's diet to enhance the nutritional suitability of the host failed to improve emergence of adult parasitoids.

20-014

IN VITRO REARING OF *CATOLACCUS GRANDIS* (HYMENOPTERA: PTEROMALIDAE) AN ECTOPARASITOID OF THE BOLL WEEVIL (COLEOPTERA: CURCULIONIDAE)

M. G. Rojas, J. A. Morales-Ramos, E. G. King
U.S. Department of Agriculture-ARS, Subtropical Agricultural Research Laboratory, Weslaco, Texas USA.

The pteromalid *Catolaccus grandis* (Burks), an obligate ectoparasitoid of the boll weevil (*Anthonomus grandis* Boheman), successfully completed development on three original meridic diets. The amino acid content of diet α was established from HPLC analysis of the hemolymph of healthy third instar boll weevil larvae. The amino acid contents of diets β and γ was established from similar analysis of haemolymph of boll weevil larvae envenomed by *C. grandis* adult females. These diets were superior to a previously reported meridic diet for *C. grandis*. Pupal weight and fecundity of females reared in the three meridic diets were lower than for females reared in vivo, but, higher than for females reared in a previously developed diet.

The biological parameters of first, second, fifth, and tenth generations of *C. grandis* reared in the γ diet were evaluated. In vitro rearing of *C. grandis* for 5 successive generations did not affect the fecundity of the adult females. However, females reared during 10 generations in artificial diet showed significantly lower fecundity than all other generations tested. Pupal weight was not significantly affected by successive generations of in vitro rearing.

20-013

COMPARATIVE HOST-SEEKING BEHAVIOR, FECUNDITY, AND LONGEVITY OF ARTIFICIALLY-REARED VERSUS HOST-REARED *DIAPETIMORPHA INTROITA* (CRESSON) (HYMENOPTERA: ICHNEUMONIDAE) WASPS

J. E. Carpenter, P. D. Greany¹
United States Department of Agriculture, Agricultural Research Service, Tifton, GA, USA -
¹ United States Department of Agriculture, Agricultural Research Service, Gainesville, FL, USA

Diapetimorpha introita (Cresson) (Hymenoptera: Ichneumonidae) is a native ectoparasitoid of *Spodoptera* spp. (Lepidoptera: Noctuidae). An artificial culture media (no insect components present) has been prepared based upon proximate analyses of pupae of the host species. The media is presented in an artificial unit intended to simulate the host pupa. *D. introita* larvae feed through an artificial membrane and develop completely on the artificial media diet.

In this study, wasps developing from the artificial diet and from host pupae were compared for their developmental time, weight, fecundity, and longevity, and their ability to seek and to parasitize hosts.

The artificial media successfully produced *D. introita* wasps in the absence of any insect host components. These diet-reared wasps demonstrated a propensity to search for and attack natural host in field cage trials. Longevity of the diet-reared wasps was comparable with the longevity of wasps reared on natural hosts.

20-015

THE SYNERGISTS FOR IMPROVING THE EFFICIENCY OF IN VITRO REARING EGG PARASITOIDS

Shi-chou Han, Qiao-xian Chen, Li-ying Li
Guangdong Entomological Institute, Guangzhou 510260, China

The method of in vitro rearing egg parasitoids has been studied by the Guangdong Entomological Institute for 20 years. More than 16 species of *Trichogramma* and *Anastatus japonicus* Ashmead now can be reared in vitro, but there are still some problems which should be solved, such as the low and unstable parasitism of "artificial host-eggs". It reduces the efficiency of producing egg parasitoids with in vitro rearing method. In recent 3 years, we found some synergists which improved the parasitizing efficiency of *Trichogramma dendrolimi*, *T. confusum*, *T. evanescens*, *T. brassicae*, *T. pretiosum* and *Anastatus japonicus* significantly on the "artificial host-eggs". They are solution of polyvinyl alcohol, gelatin, white latex, agar, cassava powder, rice flour and starch. Among them the most effective synergist is the polyvinyl alcohol.

20-016

LYOPHILIZED ARTIFICIAL MEDIA FOR *IN VITRO* REARING OF *TRICHOGRAMMA* SPP. (HYMENOPTERA: TRICHOGRAMMATIDAE)S. Grenier¹, S.C. Han², L. Chapelle¹, W.H. Liu²¹ Laboratoire de Biologie Appliquée, LA INRA, INSA Lyon Villeurbanne, France - ² Guangdong Entomological Institute, Guangzhou, China.

To make easier the rearing in artificial media for the oophagous parasitoids of the genus *Trichogramma*, it is possible to use lyophilized media. These media can be prepared when biological material such as insect hemolymph is available, and stored for one year before use.

The performance of rehydrated lyophilized media (containing pupal hemolymph of *Philosamia cynthia* or *Mamestra brassicae*) were tested with the artificial egg card systems for rearing 2 strains of *Trichogramma dendrolimi* from China (TdC) or Italy (TdI) and *Trichogramma brassicae* (Tb). All experiments had concerned 5560 artificial eggs.

Percentages of parasitization, pupation and emergence were similar or higher with rehydrated lyophilized media kept for one year, than with fresh media. Lyophilized media, centrifuged after rehydration could induce a higher egg laying rate than non centrifuged ones: little modifications of the balance between free and total amino acids could be involved. As far as centrifugation effects were concerned, performances varied according to the result parameters considered, the medium used and the strain of *Trichogramma* tested. With TdC, non centrifuged media were a little better than centrifuged ones; with TdI no significant differences were observed and with Tb, centrifuged media were better than non centrifuged ones.

Lyophilization, which does not alter the performances of the media, is a good process to keep artificial media for a long time.

20-018

DEVELOPMENT OF AN EFFECTIVE PROGRAM FOR AUGMENTATION OF *TRICHOGRAMMA* AGAINST CODLING MOTH IN CALIFORNIA

N.J. Mills

Department of Environmental Science, Policy and Management, University of California, Berkeley, CA, USA

Trichogramma platneri is an indigenous egg parasitoid of the codling moth, *Cydia pomonella*, in California and can achieve up to 60% parasitism of codling moth eggs in unsprayed orchards later in the growing season. As part of a research program to reduce reliance on insecticide treatment of codling moth, we are developing an inundative release program for *T. platneri* in combination with mating disruption in pear orchards.

The two main questions that we have investigated are (1) how does release rate affect the level of suppression of codling moth damage, and (2) how is the impact of a constant release rate affected by the number of release points in an orchard? Release rate was investigated using treatments of 0 (control), 123,500, 247,000, 494,000 and 988,000 *T. platneri* ha⁻¹ wk⁻¹ in a replicated block design of 0.2ha plots. The number of release points in an orchard was similarly investigated using a constant release rate of 494,000 parasitoids ha⁻¹ wk⁻¹, with releases in every tree, every second or every fourth tree and a non-release control. Parasitism was monitored using sentinel eggs and damage was estimated by visual inspection of fruit in the center of each plot. The results confirm the absence of parasitism from wild *Trichogramma* populations in control plots and significant reductions of fruit damage in *Trichogramma* release plots. The optimal release rate was determined to be about 400,000 parasitoids ha⁻¹ wk⁻¹ and the extent of reduction in fruit damage was directly related to the number of release points in a plot.

20-017

IN VITRO REARING OF *TRICHOGRAMMA MINUTUM* RILEY (HYMENOPTERA: TRICHOGRAMMATIDAE) FOR MULTIPLE GENERATIONS AND OTHER ADVANCES IN THE DEVELOPMENT OF AN *IN VITRO* REARING SYSTEMD. A. Nordlund, Z. Wu¹, S. M. Greenberg¹USDA, ARS, Biological Control of Pests Research Unit, Weslaco, Texas, USA - ¹ Texas A&M University Agricultural Experiment Station, Weslaco, Texas, USA

Trichogramma minutum Riley were reared on an artificial diet for 10 generation. Several quality control criteria; including adult emergence rate, development time, adult size and sex ratio; were monitored. In comparisons with *T. minutum* reared on *Helicoverpa zea* (Boddie) eggs, the values for the quality control criteria of *in vitro* reared insects was generally quite good, often better than those for *in vivo* reared insects.

Though the diet used for these studies may not be suitable for use in commercial mass rearing (development of a more chemically defined diet is in progress) of these parasitoids, it does facilitate the development of an automated mass rearing system that could be used in a commercial setting. Progress in the development of such a system, including techniques for collecting *Trichogramma* eggs, rearing to the adult stage, field release and necessary equipment will be discussed.

20-019

MATHEMATICAL MODELLING ON THE BIOLOGICAL ESTIMATES OF *TRICHOGRAMMA* SPP. AGAINST *HELICOVERPA ARMIGERA* (HB.) IN COTTON ECOSYSTEM (HYMENOPTERA: TRICHOGRAMMATIDAE - LEPIDOPTERA: NOCTUIDAE)N. Muthukrishnan, M.S. Venugopal R. Janarthanan C. Kailasam¹ and A. Sundaram¹

Department of Agricultural Entomology, 1-Department of Mathematics, Tamil Nadu Agricultural University, Agricultural College and Research Institute, Madurai, India

Simple correlation and regression techniques relating rates of parasitism to host densities do not contribute much to the understanding of host-parasitoid interaction in the field. A more feasible approach is the development of simulation model based on behavioural parameters. Data were generated in cotton field on the per cent parasitisation of *Helicoverpa armigera* eggs (artificially seeded) by *Trichogramma* spp. (*T. brasiliensis*, *T. chilonis*, *T. japonicum* and *T. pretiosum*) in three doses (1.0, 1.5 and 2.0 lakhs/ha), at different distances (2m to 50m) from the point of release and in eight directions during summer and winter of 1993 to 1994 seasons. The data were processed suitably by non-linear bounded exponential model in order to predict radius of influence, per cent parasitisation, optimum spacing between release points and benefit cost ratio for the released and extrapolated doses. The non-linear minimization algorithm by Marquardt-Lavenberg was used on a PC AT 286 computer to determine the parameters of the model. Totally eight models were worked out, a model for each *Trichogramma* spp. and season. All the eight models gave highly significant coefficient of determination (R²). Model predicted parasitisation by *Trichogramma* spp. (up to 10%) within the radius of 44.5 to 60.8m from the point of release in winter and 15.3 to 34.9 m in summer season. Parasitoid species and release densities did not influence the dispersal. Predicted order of superiority with reference to per cent parasitisation was *T. chilonis* > *T. brasiliensis* > *T. pretiosum* > *T. japonicum*. Optimum spacing between release points and benefit cost ratio estimated were 30.0 to 62.0m and 35.0 to 54.1 for winter season. This was 12.0 to 38.0m and 3.2 to 34.0 in summer. Increase in optimum spacing and decrease in benefit cost ratio were noted due to increase in release densities.

20-020

SUCCESSFUL COMMERCIAL DEVELOPMENT OF AN ENDEMIC *TRICHOGRAMMA* STRAIN AGAINST A TORTRICID LEAFROLLER IN GRAPEVINES.

D. C. Glenn, A.A. Hoffmann

School of Genetics and Human Variation, La Trobe University, Bundoora, Victoria 3083, Australia.

Inundative release of *Trichogramma* depends not only on effective parasitism of target pests in the field, but also on the ability to mass rear the selected species economically. Therefore new release programs often rely on commercially available material. However better results may be obtained if new strains are selected based on their field performance on specific target pests on the target crop after screening for acceptance of the mass-rearing host. This approach was utilised to develop an effective *Trichogramma* strain for commercial use against the Tortricid leafroller *Epiphyas postvittana* (Walker) in grapes in Australia. Four candidate species of *Trichogramma* were collected from *E. postvittana* egg masses in vineyards and assessed in the laboratory for their suitability for commercial use. This led to the selection of a strain of *Trichogramma* (*Trichogrammanza*) *carverae* which was reared on *Sitotroga cerealella* and tested in small plot trials within commercial vineyards using sentinel cards to assess potential release rates, spacing, release methods and dispersal patterns within the vineyard. These trials showed that over 75% of the egg masses in the vineyard could be parasitised by *T. carverae* at release rates of 70,000/ha with as few as 30 points per ha. Monitoring systems for *E. postvittana* were developed to help determine effective timing of releases. This study illustrates a relatively quick and inexpensive approach to the development of new strains of *Trichogramma* for commercial use that could be adapted for other agricultural systems.

20-022

THE USE OF ITS-2 DNA SEQUENCES FOR THE IDENTIFICATION OF *TRICHOGRAMMA* SPP.Richard Stouthamer, Frenk van Kan, Isabel Silva and John D. Pinto¹Department of Entomology, Wageningen Agricultural University, Wageningen, The Netherlands, ¹Department of Entomology, University of California, Riverside, CA USA

The small size and the few morphologically distinct structures in the genus *Trichogramma* has made the identification of the members of this genus difficult. At the same time *Trichogramma* wasps are mass reared and used extensively for the biological control of many lepidopteran pests. During mass rearing contamination of locally abundant *Trichogramma* species has happened, which led in some cases to the replacement of the intended species. Such contaminations have resulted in failed biological control because species specialized in the herbaceous habitat were released to control eggs in orchards. Clearly there is a need for a simplified identification system that will allow non-specialists to identify *Trichogramma* wasps. Here we will present a system based on the DNA sequence of *Trichogramma* species that will help anybody with access to a PCR-machine in the identification of specimen. We eventually hope to broaden the applicability of this system by producing an identification key based on the DNA sequence of the ITS-2 and other ribosomal genes.

20-021

TRICHOGRAMMA EVANESCENS; A BIOCONTROL AGENT AGAINST THE SUGAR-CANE BORER, CHILO AGAMEMNON (HYMINOPTERA: TRICHOGRAMMATIDAE-LEPIDOPTERA: PYRALIDAE)

M.S.T.Abbas, A.R.Hamed, M.A.Ewaise, F.A.Hassanein, M.S.I.El-Dakoury and M.M.Embaby
Plant Protection Research Institute, Dokki, Giza,

Trichogramma evanescens is reared in the laboratory on the eggs of the Angoumois grain moth, *Sitotroga cerealella*. Methods of rearing are described. The parasitoid has been released in sugar-cane fields against the sugar-cane borer, *Chilo agamemnon* since 1987. The treated area increased gradually from 20 feddan in 1987 to 11,000 feddan in 1994. The parasitoid is released only once, early in the season, at the rate of 20,000/feddan (48,000/ha). 50-79.3% reduction in rate of infestation is achieved at the end of the season. Total cost of rearing and releasing *Trichogramma* is almost three Egyptian pounds/feddan.

20-023

GREGARIOUSNESS IN EGG PARASITIDS: TOLERANCE OR LARVAL MOBILITY?

G. Boivin

Centre de Recherches et de Développement en Horticulture, Agriculture et Agroalimentaire Canada, Saint-Jean-sur-Richelieu, Québec, Canada

Insect parasitoids can be either solitary or gregarious in a given host. In solitary species of Mymaridae, the elimination of supernumerary individuals is done mostly through physical competition between the mymariform larvae. We propose that, in the *Anaphes* genus (Hym.: Mymaridae), gregariousness is a secondary character that has evolved from solitary species. The current models explaining the apparition of gregariousness have proposed a "tolerance gene" to explain the ability of several larvae to develop together in a host. This "tolerance gene" could in fact be a reduction in the mobility in the mymariform larvae that remain however able to fight. Such a model can explain the apparition and persistence of gregarious species competing with closely related solitary species.

PARASITISM OF *CLAVIGRALLA GIBBOSA* SPINOLA (HEMIPTERA: COREIDAE) EGGS BY *GRYON* SP. NR. *GNIDUS* NIXON (HYMENOPTERA: SCELIONIDAE) IN INDIA

T.G. Shanower, V. Anitha¹, V.R. Bhagwat, H. Dreyer¹

Crop Protection Division, International Crops Research Institute for the Semi-Arid Tropics (ICRISAT), Patancheru, India - 1 formerly Plant Health Management Division, International Institute of Tropical Agriculture (IITA), B.P. Cotonou, Bénin

Clavigralla gibbosa Spinola (Hemiptera: Coreidae) is an important pest of pigeonpea (*Cajanus cajan* Millsp.) in India. *C. gibbosa* females lay eggs in clusters on leaves and pods of *C. cajan*, and nymphs and adults feed on the developing seeds. Field collections over two years showed that the size of egg clusters is larger and more variable in the field (2-62 eggs) than has been reported from laboratory studies (3-33 eggs). The mean number of eggs per field-collected cluster was 18.3 compared to 6.1 in laboratory produced clusters. *Gryon* sp. nr. *gnidus* Nixon (Hymenoptera: Scelionidae) is a solitary egg parasitoid which commonly attacks *C. gibbosa* eggs on pigeonpea in India. Over the two years of this study, 13 to 68% of eggs were parasitized in each sampling period. Of the more than 40,000 eggs collected, *G. sp. nr. gnidus* parasitized 41.8%. The proportion of egg clusters parasitized varied from 22 to 100% and increased through the season. In 25 of 30 standard weeks sampled, more than 50% of egg clusters were parasitized, indicating the strong host finding ability of this species. The relationship between egg cluster size and parasitization showed a strong positive correlation; larger clusters were more frequently parasitized than smaller clusters. Less than 10% of egg clusters had all eggs parasitized by *G. sp. nr. gnidus*. The average size of egg clusters in which all eggs were parasitized was 15.2 eggs.

INFLUENCE OF VARIOUS EGG HOSTS ON THE BIOLOGY OF TRICHOGRAMMA CHILONIS ISHII (HYMENOPTERA : TRICHOGRAMMATIDAE)

R.S. Rath, P. Ram

Department of Entomology, CCS Haryana Agricultural University, Hisar, Haryana, India.

Observations were made on some biological parameters of *T. chilonis* reared on the eggs of *Helicoverpa armigera* (Hb.), *Amsacta moorei* Butler* and *Corcyra cephalonica* Stainton. Amongst different hosts, *E. vittella* was preferred by the parasitoid both under choice and no-choice conditions. Per cent adult emergence was highest when the parasitoid was reared on *C. cephalonica*. Greater proportion of females in the parasitoid progeny emerged from the eggs of *A. moorei*. Parasitoids emerged from the eggs of *E. vittella* were more fecund and long lived. Interestingly, parasitoid progenies from larger eggs (of *A. moorei*) were less fecund and short lived necessitating further investigations.

20-027

GENETIC MAPPING OF TRICHOGRAMMA BRASSICAE GENOME WITH RAPD MARKERS

V. Laurent, F. Vanlerberghe - Masutti, E. Wajnberg, B. Mangin*, B. Goffinet*
Laboratoire de Biologie des Invertébrés. INRA. Antibes. France.
* Laboratoire de Biométrie. INRA. Toulouse. France.

Although biological control represents a successful pest control strategy, selective breeding programs have hardly begun for natural enemies, such as the parasitoid wasp *Trichogramma*. Since genetic maps provide a powerful tool for accelerating breeding through marker assisted selection, a genetic map of *Trichogramma brassicae* genome is under construction with RAPD markers. Later, location of the genes controlling fecundity and longevity will inform us about the feasibility of QTL (Quantitative Trait Loci) identifications of characters involved in the biological control efficiency.

Three F2 mapping populations of 100 individuals each were constructed. These populations are polymorphic for both DNA and biological traits. 192 10-bases random primers were screened for polymorphism between parental lines and homogeneity inside lines. A total of 116 RAPD fragments (i.e. markers) obtained from 74 primers were selected for mapping.

At present, segregation of a total of 60 RAPD markers was scored on the various mapping populations. As preliminary results show a good colinearity of the 3 genetic maps, and thus assess the reliability of the RAPD markers to construct a genetic map of *Trichogramma brassicae* genome, a composite map of 51 markers has been constructed. Four groups which putatively correspond to the 4 largest chromosomes out of 5 were identified. More complete genetic maps will be presented.

20-028

EFFECT OF DENSITY RELEASE OF *USCANA SENEX* GRESE (HYMENOPTERA: TRICHOGRAMMATIDAE) ON THE PEA WEEVIL EGGS PARASITIZATIONM. Gerding¹ and L. Hormazabal²¹Centro Regional de Investigación Quilamapu-INIA, Chillán, Chile.²Facultad de Agronomía, Universidad de Concepción, Chillán, Chile

An experiment was conducted to evaluate the effect of four different release densities of *Uscana senex* on the parasitism ability of *Bruchus pisorum* eggs. Colonization and pea seed damage reduction were evaluated. The total release treatment were 1.92, 3.84, 7.68 and 15.2 millions of *U. senex* ha⁻¹. Each treatment considered two release per week from beginning of flowering to 100 % of full pods, unto complete the total of individual per treatment. The rate of parasitism obtained in the treatments with parasitoids ranged between 49.8 % and 82.1%.

U. senex exhibited an important dispersion ability and the eggs parasitism rate decreased as the distance from the focus of release increase. Seed damage was reduced in 70% with the highest release density as compared with the check

20-030

USE OF TRICHOGRAMMA IN *RHYACIONIA BOULIANA* CONTROL IN CHILEMarcos Gerding¹, Ernesto Cisternas² and Cecilia Céspedes¹¹Centro Regional de Investigaciones Quilamapu, Chillán Chile.²Centro Regional de Investigaciones Remehue, Osorno Chile

Since 1985, *Rhyacionia bouliana* (Lepidoptera: Tortricidae) has been the main pest of *Pinus radiata* forest in Chile. Its incidence has been increasing every year, with a significant economic injury, riching up to 50% of timber production. The biological control program has been oriented to introduce *Orgilus obscurator* (Hymenoptera: Braconidae) but, its mass rearing is highly time consuming. The use of *Trichogramma* spp., as biological control complement, could be a useful alternative for the pine growers. Recently, a native *Trichogramma* from *R. bouliana* eggs was collected in the central-south area of Chile. Under laboratory conditions this parasitoid was mass reared and its parasitic ability compared with *T. dendrolimi* and *T. telengai* strains, introduced from Bulgaria. The results were favorable to the native trichogramma. In the last season, the field release studies, about density and opportunity, has been done only on this native egg parasitoid.

20-029

BIOLOGICAL CONTROL OF THE DIAMONDBACK MOTH BY TRICHOGRAMMA CHILONIS

K. Miura, M. Kobayashi

Laboratory of Insect Pest Control, Chugoku National Agricultural Experiment Station, Fukuyama Hiroshima, Japan

We have been investigating the possibility of a biological control program against the diamondback moth (DBM), *Plutella xylostella*, using *Trichogramma chilonis*. Here we would clarify the properties of *T. chilonis* and examine how to utilize them. *T. chilonis* females which developed in DBM eggs showed a lower fecundity than those developed in *Ephestia kuehniella* for mass rearing host. *T. chilonis* females which developed in DBM egg did not have a markedly higher reproductive capacity. Under conditions of high temperature, a smaller percentage of emergence of the progeny would be expected. These results indicate that the inundative method would be better than inoculative release for control of DBM using *T. chilonis* developed in alternative hosts in the laboratory in warmer temperate zones.

To simulate the population dynamics of the system of the DBM and *T. chilonis*, it was made a simple simulation model described as the Leslie Matrix model based on following behavior. *T. chilonis* would oviposit in a parasitized host after release under some conditions (e.g., higher parasitoid densities). *T. chilonis* could attack DBM eggs of all ages, but the intermediate age host is most parasitized in all age-hosts. In response to a contaminated area where DBM scales and secretions present, a *T. chilonis* female exhibits a response involving walking at a reduced speed. DBM scales or secretions elicited the oviposition behavior of *T. chilonis* females. From functional response of *T. chilonis* to DBM eggs, rate of attacking increased rapidly as the DBM egg density increased, but the curve levelled off at higher host densities. The model indicated that an optimal time and optimal density of releasing parasitoids exist in the introduction programme of *T. chilonis*.

20-031

HOST LOCATION BY PARASITOID: ASSESSMENT OF PROFITABILITY

L.E.M. Vet

Department of Entomology, Wageningen Agricultural University, Wageningen, The Netherlands.

Like all foraging animals, insect parasitoids have to cope with temporal and spatial variability in resources. Parasitoids make flexible use of chemical information from their host and its food to optimize life time host encounter rate. In contrast to what is assumed in many foraging models, foraging parasitoids are not omniscient but need to learn through experience where hosts are and which (micro)habitats are the most profitable. Chemical host and plant cues can give information on the presence and even on the relative density of hosts, and the reliability of this information is enhanced through learning. It is known that experience can lead to induced preferences for important foraging cues. It is less known that parasitoids also decide to ignore experienced variation and that they generalize learned information. I will present data on the assessment of habitat profitability e.g. showing that the expression of preference is influenced by the informational state of the parasitoid, i.e. by whether the animal has 'complete' or 'incomplete' information on the profitability of different microhabitats.

20-032

THE ROLE OF PLANT CHEMICALS IN HOST SELECTION BY PARASITIC INSECTS.

J. Takabayashi, M. Horikoshi¹, S. Yano, N. Ohsaki², R. Yamaoka¹, M. Dicke³ and Y. Sato⁴

Laboratory of Ecological Information, Graduate School of Agriculture, Kyoto University, Kyoto 606-01, Japan - 1 Department of Applied Biology, Kyoto Institute of Technology, Kyoto 606, Japan - 2 Entomological Laboratory, Faculty of Agriculture, Kyoto University, Kyoto 606-01, Japan - 3 Department of Entomology, Agricultural University, Wageningen, The Netherlands - 4 Kyoto College of Medical Technology, Sonobe, Kyoto 622, Japan

Parasitic insects use several chemicals of host food plant origin as cues of presence of hosts. The functions of such cues differ according to their volatility: parasitoids can detect volatile cues at a distance from a host food plant whereas they can detect nonvolatile cues through contact chemoreception. In addition, plants produce these chemicals either constitutively or in response to herbivore damage. The damage by host feeding may induce a plant to produce specific compounds. Such host-induced plant chemicals seem to be more reliable cues for the parasitoids on the presence of host on the plant than constitutively produced chemicals. We will report on the role of such plant chemicals in the host selection by parasitic wasps in the following two systems.

(1) Crucifer plants - *Pieris rapae* larvae - *Cotesia glomerata*

(2) Corn plants - *Pseudaletia separata* larvae - *Cotesia kariyai*

20-034

PLANT-MEDIATED SUITABILITY: DOES HERBIVORE PERFORMANCE DETERMINE PARASITOID FITNESS? B. Benrey. Center for Ecology, Universidad Nacional Autónoma de México (UNAM).

A growing number of studies suggest that plants can dramatically influence the interactions between herbivorous insects that feed on them and the natural enemies of these herbivores. Features of plants, such as allelochemistry, nutrients, and morphology, can affect herbivore-enemy interactions by influencing the enemies either directly or indirectly.

Systems in which wild and cultivated species coexist provide ideal models to study interactions among the three trophic levels. Crop plants and ornamentals which have been the subject of artificial selection may have altered allelochemistry and nutrient content. Insects that feed on these plants, as well as the natural enemies that attack these insects have been forced to adapt to this plant variability. I will present the results from studies conducted on two systems; one involving the herbivore *Pieris rapae* (Lep: Pieridae) and its parasitoid *Cotesia glomerata* (Hym: Braconidae) and the other involving the seed eating beetle *Zabrotes subfasciatus* (Col: Bruchidae) which is parasitized by *Stenocorse bruchivora* (Hym: Braconidae). In these studies we examined the influence of plant species on the performance and host location behavior of parasitoids that were offered hosts on cultivated and wild plant species. Results from these two studies show that overall, the plant species on which hosts perform best, also provide the most suitable resource for the parasitoids. It was found that, parasitoid fitness is increased by parasitizing the most vigorous hosts. I discuss how natural selection may have operated on parasitoids to locate plants with hosts in which their performance is maximized.

20-033

HERBIVORE-INDUCED EMISSIONS OF PARASITOID ATTRACTANTS BY PLANTS

Ted C.J. Turlings

Institute of Zoology, University of Neuchâtel, Rue Emile-Argand 11, CH-2007, Neuchâtel, Switzerland

A multitude of studies on tritrophic level interactions have shown that plants can promote the presence of natural enemies of herbivores. Particularly, the phenomenon that plants emit specific odors in response to herbivore attack has received considerable attention. One measurable consequence of the odor emissions is the attraction of parasitic wasps, which is suggested to be one of the functions of the plant-produced odor. A comparison of herbivores that employ different feeding strategies revealed considerable differences in the emissions that they induce plants to emit. Some insects may be able to avoid induction and therefore reduce the chances that they are found by their natural enemies. The additional consequences of herbivore-induced emissions of plant volatiles and strategies that herbivores may employ to avoid these consequences are discussed.

20-035

FORAGING FOR HOST AND FOOD RESOURCES: COMPARISONS, CONTRASTS, AND INTERACTING INFLUENCES

W.J. Lewis, K. Takasu¹

USDA-ARS, P. O. Box 748, Tifton, GA, USA, -1 Kobe University, Kobe 657, Japan

Parasitic insect adults must locate food to meet their short-term nutritional needs as well as find hosts for reproductive purposes. A knowledge of how females deal with the often competing needs for these two vital resources is essential to understanding parasitoid foraging strategies. Studies show that foraging females need periodic nectar and/or pollen meals, and that availability and accessibility of food in a target area strongly affects their retention and host finding efficacy.

The use of olfactory and visual cues from plants, usually enhanced by learning, play important and sometimes interacting roles in a female parasitoid's search for food and hosts. Thus, the provision by plants of floral and extrafloral nectar along with associated foraging signals play a crucial role in the tritrophic interplay of plants, herbivores and parasitoids. This broader understanding of tritrophic level interactions that encompasses parasitoid food considerations can enhance our ability to design effective biological control strategies.

20-036

RELIABILITY VS. DETECTABILITY AS A FORAGING CONSTRAINT FOR FORAGING PARASITIDS AND PREDATORSMarcel Dicke

Department of Entomology, Wageningen Agricultural University, Wageningen, The Netherlands.

Carnivorous arthropods such as predators and parasitoids that search for herbivores can potentially use a variety of chemical cues during various phases of the foraging process. In long-distance searching volatiles cues are the most important ones. Such cues may originate from the herbivore and from its food plant, but these two groups of volatiles differ in detectability and reliability.

The most important volatile cues that are used by carnivores, are herbivore-induced synomones that originate from the food plant of the herbivores. These chemicals, that are emitted by herbivore-damaged plants are highly detectable. In several cases they are highly reliable indicators of the herbivores that damage the plant, in others such reliability has not been recorded.

I will review knowledge about the reliability of herbivore-induced synomones. The major question is whether the reliability of herbivore-induced plant volatiles is idiosyncratic or can a pattern be found? How do parasitoids and predators deal with non-specific plant volatiles in finding the right herbivore species or instar.

20-038

THE ROLE OF VISUAL AND MECHANOSENSORY CUES IN HOST LOCATIONFelix L. Wäckers

Institute of Plant Sciences, Applied Entomology, Swiss Federal Institute of Technology, ETHZ/NW, CH-8092 Zürich, Switzerland.

In addition to chemical stimuli, physical stimuli also play a crucial role in host searching by hymenopterous parasitoids. Parasitoids were found to use colour, shape, movement and mechanosensory cues (vibrations) for orientation. These physical stimuli may either stem from the host habitat, directly from the host, or (in the case of echolocation) from the parasitoid itself.

While some of the responses to visual and mechanosensory stimuli are innate, it could be demonstrated that parasitoids employ associative learning to incorporate additional physical stimuli into their search profile. These learned responses allow parasitoids to concentrate their search on those parts of the habitat that are most profitable in terms of host encounters.

Examples of visual and mechanosensory orientation will be presented and their relative significance in host finding will be discussed.

20-037

SOURCES OF INTER-INDIVIDUAL VARIABILITY OF ODOR LEARNING PERFORMANCES IN *LEPTOPILINA BOULARDI* (HYMENOPTERA: EUCOILIDAE), PARASITOID OF *DROSOPHILA*.R. Pérez-Maluf¹, L. Kaiser¹, E. Wajnberg²

1. Laboratoire Neurobiologie Comparée des Invertébrés, INRA/CNRS, 91440 Bures sur Yvette, France. 2. Laboratoire de Biologie des Invertébrés, INRA, 06606 Antibes, France.

As in many parasitoid species, behaviors leading to host location by females *Leptopilina bouleardi* are triggered by the perception of chemicals cues, which depends on learning processes. Odors perceived during oviposition are memorized through associative learning, and consequently trigger oriented locomotion and ovipositor search of a substrate. Such changes in odor responses would increase the probability to locate a suitable host: associative learning is considered as a key process for the adaptation to varying host resources and for successful parasitism. Ability for associative learning varies greatly among individuals, as seen from laboratory studies conducted on *L. bouleardi*, so we started to search for the sources of such a variability. We developed a bioassay to quantify individual learning performances based on the observation of odor-conditioned probing response, characterized by several parameters. The relative importance of genetic versus environmental variability of these parameters was evaluated using isofemale lines. Because most variability was environmental, the influence of two non-genetic factors, mating and oviposition experience, was investigated. Possibilities to control better the variability of odor learning involved in host selection will be discussed.

20-039

LEAF VIBRATIONS AND NEAR FIELD AIR DISPLACEMENT IN A LEAFMINER-PARASITOID SYSTEMJ. Casas, S. Bacher¹, J. Tautz² and R. Meyhöfer¹

University of Tours, Tours, France- 1 Swiss Federal Institute of Technology ETHZ, Zürich, Switzerland- 2 University of Würzburg, Würzburg, Germany.

The parasitoid *Sympiesis sericeicornis* (Hym. Eulophidae) changes its foraging behaviour on the mine when its host, the apple leafminer *Phyllonorycter malella* (Lep. Gracillariidae), initiates vibrations either by moving or escaping (Meyhöfer et al. *Physiol. Ent.* 19: 349-359, Meyhöfer et al. *submitted*). The host also reacts to the vibrations produced by the foraging parasitoid (Bacher et al. *Physiol. Ent.* *in press*). How specific or common these vibrations are in the environment of the leafminer was studied using Laser Vibrometry. Vibrations produced by simulated rain and wind were of a different nature to those produced by the parasitoid. Moving insects impart forces of varying intensities and duration to the leaf. It is therefore difficult to assess from such data how far leaf properties modify vibratory signals. Using impacts made by small metal balls, the ringing signature of the leaf was identified in a signal and it was established that a gradient in intensity and frequencies composition exists over the entirety of a leaf. Foraging parasitoids of endophytic hosts may use air displacement triggered by plant vibrations, in turn produced by moving hosts. Measurement using Laser Vibrometry coupled with Laser Anemometry around vibrating leaves confirmed that near field air displacement is a potential source of information to foraging parasitoids and hence deserves closer analysis.

20-040

EGG LIMITATION IN PARASITOIDS: EVIDENCE FROM FIELD STUDIES AND IMPLICATIONS FOR HOST SELECTION

G.E. Heimpel

Department of Entomology, University of Wisconsin, Madison WI 53706, USA

Recently-developed theory predicts that natural selection should favor a non-trivial risk of female parasitoids becoming egg-limited (i.e. depleting their egg supply). In this presentation, I address three questions related to this hypothesis. First, is there empirical support for egg limitation from field studies of parasitoids? Second, should we expect the risk of egg limitation to differ in natural versus agricultural populations of parasitoids? And third, what are the consequences of egg limitation for host selection?

The few studies aimed at uncovering the prevalence of egg limitation have all supported the hypothesis that egg limitation occurs in the field. Egg limitation apparently occurs under both natural and agricultural conditions, and it has been proposed that it may be more extreme under agricultural conditions, where host availability is likely to be high. Also, egg limitation occurs in pro-ovigenic species (where it is permanent), as well as in synovigenic species, where it may be temporary.

Parasitoids are predicted to be increasingly 'choosy' with respect to host selection as the risk of egg limitation increases. Evidence for increased choosiness under conditions of impending egg limitation is mounting, although some studies have failed to show such an effect.

20-042

STRATEGIES INVOLVED IN THE LOCATION OF HOSTS BY THE APHID PARASITOID *APHIDIUS ERVI* HALIDAY (HYMENOPTERA: BRACONIDAE: APHIDIINAE)

W. Powell¹, F. Pennacchio², G.M. Poppy¹, E. Tremblay³

¹Entomology & Nematology Dept., IACR-Rothamsted, Harpenden, U.K. - ²Dipartimento di Biologia, Difesa e Biotecnologie Agroforestali, Università della Basilicata, Potenza, Italy. - ³Dipartimento di Entomologia e Zoologia Agraria, Università di Napoli, Portici, Italy.

The parasitoid *Aphidius ervi* Haliday uses both semiochemical and physical cues to locate its main host, the pea aphid *Acyrtosiphon pisum* (Harris). Recent wind tunnel studies have demonstrated the importance of plant volatiles in the initial, long range host finding responses, particularly volatiles induced by aphid feeding damage. However, the parasitoid can distinguish between plants damaged by host aphids and those damaged by the non-host *Aphis fabae* (Scop.). There is also evidence from wind tunnel bioassays that the host-induced plant volatiles are produced systemically throughout the plant. Volatile chemical entrainment and identification techniques are being used to isolate and identify the compounds involved in these responses. Previous experiences with hosts or host-related cues heighten the responses to host-induced plant volatiles and trigger other responses via conditioning and/or associative learning. Contact cues appear to be used in host recognition and acceptance and bioassays have indicated the presence of such cues in the host cuticle and cornicle secretion. Visual cues also play a role in host location and recognition, with colour being an important short range cue. The significance of these findings for the manipulation of adult parasitoid behaviour to enhance pest control and their implications for host selection and evolution within the Aphidiinae will be discussed.

20-041

THE INFLUENCE OF COMPETITION BETWEEN FORAGERS ON CLUTCH SIZE DECISIONS IN AN INSECT PARASITOID WITH SCRAMBLE LARVAL COMPETITION.

Marcel E. Visser

Netherlands Institute of Ecology, Heteren, The Netherlands

The effect of competition between ovipositing females on their clutch size decisions is studied in animals that lay their eggs in discrete units of larval food (hosts). In such species the effect of competition depends on the form of the larval competition within such units. In parasitoids insects, there might either be contest (solitary parasitoids) or scramble competition (gregarious parasitoids) between larvae within a host. For gregarious parasitoids, a decreasing clutch size with increasing competition between foragers is predicted. This prediction is tested in experiments using the parasitoid *Aphaereta minuta*. Parasitoids were either kept alone or in groups of 4 before the experiment, in which they were introduced singly in a patch containing unparasitized hosts. Animals kept together laid on average clutches of 0.74 eggs smaller than females kept alone (average clutch is 5.3), thereby confirming the prediction. Clutch size decreased with encounter number, which might be due to the adjustment of the female's estimate of the encounter rate with hosts. Finally, the results are compared with those reported for solitary parasitoids (that have scramble larval competition), for which it is predicted that the clutch size will increase with increasing levels of competition between females. In some species of solitary parasitoids, a clutch of 2 eggs is laid in a host under intra-specific competition between females. In other species the occurrence of self-superparasitism, which can be viewed as a clutch size adjustment, increases with increasing competition. Thus, as predicted, with increasing intra-specific competition between adult females, clutch size increases in solitary parasitoids and decreases in gregarious parasitoids.

20-043

HOST SELECTION STRATEGIES USED BY EGG PARASITOIDS

F. Bin¹, S.B. Vinson², S. Colazza¹, E. Conti¹

¹Istituto Entomologia agraria, Università di Perugia, Perugia, Italy - ²Department of Entomology, Texas A&M University, College Station, TX USA.

Host eggs represent for parasitoids a small finite source, undergo major and often quick internal changes, probably lack internal defences, are immobile, and derive their protection from the preceding stage: the adult. Therefore egg parasitoids, as other idiobionts, use an array of cues from plants, host adult and host egg and have developed diverse and often unique host relationships. They are also important biocontrol agents. Several aspects are reviewed as follows.

Host associations focus on host habitat and plant, oviposition sites, host egg characteristics in several groups. Chemio-physical cues are examined in different biotaxonomic and tritrophic systems together with host preference and alternate hosts.

Efficiency and constraints are discussed with regard to discovery and exploitation of host and its patch, to impact and secondary sex-ratio of parasitoid, and to suitability of plant-host complex.

Novel associations show a success rate not significantly different from coevolved ones. These results cannot be explained without considering the equivalences in recognition factors between old and new potential hosts which make host shifting possible.

Basic studies of chemio-physical cues mediating host selection behavior should aim at defining predictability of specificity in order to test efficacy and safety of these parasitoids and transferring this to biocontrol programs.

20-044

THE EGGS OF THE PARASITOIDS.**J.-P. N  non and G. Boivin**

Laboratoire d'Ecobiologie des Parasito  des, Universit   de Rennes 1, 35042 Rennes Cedex, France. 1- Centre de Recherches et de D  veloppement en Horticulture, Agriculture et Agroalimentaire Canada, Saint-Jean-sur-Richelieu, Qu  bec, Canada

The insect parasitoids evolved from species with different life histories and from several types of habitat. Different egg types evolved depending on the host and habitat exploited by these parasitoids. Among the constraints acting on the egg, the oviposition site (endo- ectoparasitoids or host found by mobile first-instar larva) and the length and type of ovipositor appear most important. Species from different groups, among the Hymenoptera but also the Coleoptera, Diptera and Trichoptera, facing the same situation may have evolved the same adaptations through convergence. The egg characteristics examined in species representative of these groups were the chorion, the envelopes and the vitelline content along with functional aspects such as the egg plasticity at oviposition and resistance to desiccation and host defenses.

20-046

A COMPARISON OF THE EXOCRINE GLANDS OF PARASITIC HYMENOPTERA AND THEIR BIOLOGICAL SIGNIFICANCE

S. Bradleigh Vinson
Department of Entomology, Texas A&M University, College Station, TX 77843 USA

Hymenoptera harbor a variety of exocrine glands generally of ectodermal origin. These glands serve important functions in the biology of parasitic hymenoptera. Many of these glands are found in the head and are thought to be associated to feeding. Other glands are located in the abdomen and are assumed to be associated with oviposition. Although most exocrine glands are of ectodermal origin, for example, those associated with reproduction, such as Dufour's gland, the poison gland and glands associated to the lateral or common oviduct, follicular cells are of mesodermal origin, but can provide exocrine secretions. These and other glands to be discussed include the pygidial or Hagen's glands, and other glands in the abdomen suspected to produce exocrine secretions. The occurrence and morphology of these glands show considerable variation among the various taxa of parasitic hymenoptera. This variation and the function of these glands, when known, is discussed. However, this discussion will not include glands associated with the antennae, which will be included elsewhere.

20-045

MOUTHPART STRUCTURE AND FUNCTION IN INSECT PARASITOIDS, WITH PARTICULAR REFERENCE TO FEEDING**M.A.Jervis, F.S.Gilbert¹**

School of Pure and Applied Biology, University of Wales, Cardiff, Cardiff, UK -
1 Department of Life Science, University of Nottingham, Nottingham NG7 2RD, UK

The diversity of mouthpart structure among parasitoids is examined. The mouthparts of some Braconidae (so-called 'exodonts': Alysiinae, Dacninae) are modified for the purpose of escape from the host's puparium. In *Psilus* species (Diapriidae) the mandibles have a long, wide sweep, and are similarly employed. The majority of hymenopteran parasitoids are able, using the mouthparts, to lap up both wet honeydew and nectar from exposed nectaries. They can also easily ingest pollen grains. Perilampidae and Eucharitidae appear to use their digitate labrum to avoid ingesting pollen grains that often contaminate nectar. Adults of some Ichneumonidae (*Lapton*, *Agathophiona*, *Rynchophion*, *Gonolochus*, *Agathilla*, *Certonotus*) and Braconidae (species of *Bracon*, *Agathis*, *Cardiochiles* and *Chelonus*) have elongated suctorial mouthparts (labiomaxillary complex) (= apomorphic condition) that they use to consume concealed floral nectar.

The plesiomorphic condition for the mouthparts of Cyclorrhaphan Diptera (e.g. many Tachinidae) is a fleshy labellum with numerous pseudotracheae and their overlying channels. These structures are efficient in the ingestion of either honeydew or nectar (extrafloral or unconcealed floral), but can also easily serve in the removal and ingestion of pollen from the anthers of flowers. Members of a much wider range of families than in parasitoid Hymenoptera have elongated mouthparts (Acroceridae, Conopidae, Bombyliidae, Nemestrinidae, Phoridae, Pyrgotidae, Tachinidae); the labellum is reduced in these insects. Such mouthparts are associated with the exploitation of flowers that have deep corollae and sugar-rich nectar.

We propose areas for future research, including complementary behavioural studies.

20-047

ANTENNAL SENSORY AND SECRETORY STRUCTURES IN PARASITOID HYMENOPTERA**N. Isidoro, F. Bin, S. Colazza, S.B. Vinson¹**

Institute of Agricultural Entomology, University of Perugia, Perugia, Italy - 1 Department of Entomology, Texas A&M University, College Station, TX USA

The antennae of Hymenoptera parasitoid, previously considered only as receivers of signals, are also emitters for intra- and interspecific communication. This revision describes sensilla and glands, suggesting their possible function and comparing them in different taxa. General features of all types of sensilla are revised following the conventional classification into aporous, uniporous and multiporous sensilla. For multiporous types, ultrastructural investigations have revealed special features which define some new sensilla, e.g. female gustatory sensilla with a specialized multiporous area innervated by very many sensory neurons. Secretory structures, belonging to class 1 or 3 gland type, may be present in one or both sexes. The gland release site may be apparent or inconspicuous and may be found on modified or unmodified antennomeres. In males the release site may be dorsal, ventral or lateral. In females it is generally dorsal with the exception of two groups which have ventral accessory glands associated with multiporous gustatory sensilla. Using morphological data, topography and behavioral observations, the role of some sensilla and glands is discussed. These structures are likely involved in both physical and chemical aspects of mate and host recognition.

20-048

Ovipositor structure and function in the parasitic Hymenoptera.

Donald L.J. Quicke and Anne LeRalec

Biology Department, Imperial College, Silwood Park, Ascot, SL5 7PY, U.K.; Ecole Nationale Supérieure Agronomique de Rennes, Zoologie, 65 rue de Saint-Brieuc, F 35042 Rennes cedex, France

The ovipositor and oviposition behaviour have been extremely important in the evolution of the Hymenoptera, and especially in the evolution of the parasitoid life history. In this chapter we review the functional anatomy of the hymenopteran external ovipositor system. The basic structure is derived from paired appendages of the 8th and 9th abdominal segments has been preserved throughout the order, and comprises an upper valve (2nd valvula) which is interlocked with a pair of lower valves (1st valvula) together with a pair of protective sheaths (3rd valvula). In nearly all non-aculeate Hymenoptera, the tubular canal formed between the upper and lower ovipositor valves serves for the passage of eggs and other secretions (e.g. venoms, lubricants, marking pheromones, feeding tube materials). The ovipositor valves contain living tissue including nerves, tracheae, and fat cells, but lack intrinsic musculature, and so substrate penetration and oviposition rely on muscles within the metasoma that attach to the bases of the ovipositor valves and associated sclerites. Some taxa have evolved telescopic ovipositor mechanisms that involve modified posterior metasomal segments, and some are able to steer their ovipositor tips to facilitate host location. The apices of the ovipositor valves are usually serrated, but little is known of 'drilling' mechanics. Passage of the egg along the egg canal is assisted by too-and-fro movements of the valves and is believed to result from ratchet-like action of the cuticular scales present on the egg canal wall. The microsculpture varies along the ovipositor within a species, and between species. The tip of the ovipositor and the ovipositor sheaths have sensillae. Mechanoreceptors are typically present on the 2nd valvifers; proprioceptors on 1st and sometimes 2nd valvulae are probably involved in detecting movements of the different pieces of the ovipositor during egg laying. Various sensilla morphotypes on the 3rd valvulae differ between species in number in accordance with use of 3rd valvulae in host examination. First and 2nd valvulae have various sensilla, including mechanoreceptors and contact chemoreceptors which are probably involved host discrimination and acceptance, and egg placement. Compared with others insect groups, sense organs on female genitalia in parasitic wasps are characterised by i) reduced size, ii) peculiar morphological types, iii) larger proportion of gustatory compared to mechanoreceptors. Some of the above features may be phylogenetically informative, whilst other characters are associated with particular types of hosts or host substrates, and exhibit adaptive convergence.

20-050

DIAPAUSE IN THE PREDACEOUS HETEROPTERAJ.R. Ruberson¹, T.J. Kring²¹University of Georgia, Tifton, GA, USA.²University of Arkansas, Fayetteville, AR, USA.

Heteropteran predators in the Temperate Zone must cope with predictable times of each year that are refractory to their development and reproduction: typically winter and portions of the spring and fall. Many species of heteropteran predators pass this period in a state of diapause. Most diapausing species do so as adults, although some diapause in nymphal stages and a few as eggs. Predaceous heteropterans usually overwinter individually in sheltered habitats, such as in leaf litter, under tree bark, or in winter grasses. Overwintering mortality of these species is not well known, but appears to be high for those species studied to date. Photoperiod serves as a primary cue for diapause induction, although its effect may be modified by temperature and, in at least one case, by the quality of prey. Sensitivity to diapause-inducing photoperiods occurs in either the nymph or the adult, or in some combination of both the nymphal and adult stages. When sensitivity occurs in the nymphal stages, it is restricted to the late instars for species studied thus far. Short photoperiods serve to maintain diapause in the predaceous Heteroptera, although low temperatures can interact with short photoperiods to maintain diapause; conversely, long photoperiods and high temperatures serve to maintain diapause. At least several species of predaceous Heteroptera feed while in diapause; thus prey availability may be important in selecting an overwintering site. Understanding diapause can be valuable for commercial production, where diapause can be an impediment to rearing and application, or a valuable tool for storing or stockpiling predators.

20-049

FUNCTIONAL MORPHOLOGY AND THE PRACTICAL USE OF PARASITOIDS IN BIOLOGICAL CONTROLJ. LaSalle, L.M. LeBeck¹International Institute of Entomology, London, UK - 1
Department of Entomology, University of Hawaii at Manoa, Honolulu, Hawaii, USA

Biological control programmes are reviewed to assess the impact of studies on various aspects of functional morphology of parasitoids to the success of the projects. Examples are presented where problems in the implementation of successful biological control were solved through the previous knowledge or subsequent study of functional adaptations of parasitoids. Justification is provided for continuing applied studies of parasitoid morphology, behaviour, and biology. Recommendations are made for priority areas of future research activity.

20-051

MANAGEMENT OF PREDACEOUS HEMIPTERANS WITH SEMIOCHEMICALS: PRACTICE AND POTENTIAL

J.R. Aldrich and Prapai Puapoomchareon

USDA-ARS Insect Chemical Ecology Laboratory, Beltsville, MD USA

Two ongoing research projects involving predaceous hemipterans will be discussed: 1) pheromone-mediated augmentation of the spined soldier bug (SSB), *Podisus maculiventris* (Say) (Pentatomidae), for suppression of the Colorado potato beetle (CPB) and, 2) the isolation and identification of the suspected sex pheromone of *Orius insidiosus* (Say) (Anthrenidae).

The SSB overwinters in the adult stage, and a synchronized, massive emergence occurs just prior to the bud burst of deciduous trees in the eastern U. S. The commercialized, male-produced pheromone of this predator (attractive to both sexes and nymphs) is being used to harvest wild adults in pheromone-baited traps to mass-produce and manipulate young predators for augmentative biological control. Results after the second year of a 3-year project indicate that the average potato plant defoliation by the CPB in May was 20% in the plots where the soldier bugs were released (ca. 5 nymphs/plant), and 44% where the bugs were not released (9 potato plots; 500 m²/plot; ca. 1036 plants/plot). The average potato plant in the release plots produced 454g of tubers whereas production in the control plots was 60g, an 87% yield reduction. For *Orius insidiosus*, Y-tube olfactometer bioassays showed that males are attracted to volatiles from virgin females. Suspected attractants were isolated by whole-body extraction, aeration, and microdissection. Three novel female-specific compounds have been identified: (2E,7)-octadienal, (2E,7)-octadienoic acid, and (2E,9)-decadienal. Further laboratory and field tests are planned to determine if these compounds are attractive to conspecifics.

20-052

PHYTOPHAGY IN PREDATORY HETEROPTERA AND ITS IMPLICATIONS FOR BIOLOGICAL CONTROL

M. Coll

Department of Entomology, Faculty of Agriculture, The Hebrew University of Jerusalem, Rehovot, Israel

Many species of predatory Heteroptera are known to feed on plants, as well as prey (omnivory). Plant resources enhance the fitness of these predators not only in the absence of prey but also as supplements to a carnivorous diet. Studies show that plant species differ in their suitability for the development, survival, and reproduction of *Orius insidiosus*. On some plants, the oviposition preference of the females was correlated with the plants' suitability for the nymphs. A simple model shows that populations of plant-feeding predators and their prey are less stable when the omnivore feeds on suitable plant resources. Data on the response of omnivorous Heteroptera to plant diversity in the habitat suggest that the instability of systems with plant-feeding predators is local. Apparently, these omnivores respond in an opportunistic manner to changes in the availability of prey and plant resources. To enhance the efficacy of predatory bugs, yet prevent possible damage to crops, biological control programs need to consider the unique feeding habits of many promising heteropteran agents. Also, plant resources could be utilized as food, oviposition substrates, and delivery media in augmentative release programs.

COLONIZATION AND SEASONAL DYNAMICS OF *ORIOS INSIDIOSOS* IN NORTHERN CLIMATESA. Andow

ABSTRACT NOT RECEIVED

20-053

POPULATION DYNAMICS OF *ORIOS* AND ITS RELEVANCE TO BIOLOGICAL CONTROLYoshimi Hirose

Institute of Biological Control, Faculty of Agriculture, Kyushu University, Fukuoka, Japan

Although *Orius* species are known to be effective control agents of various pests, the population dynamics of *Orius* are examined in search of mechanisms involved in the biological control of thrips pests in particular. A population study of *Orius* spp. and the pest *Thrips palmi* on eggplant in home and truck gardens in Japan demonstrates that the more abundant the population of *T. palmi* per home garden, the more abundant the population of *Orius* spp. per home garden. There is suggestive evidence that this numerical response of *Orius* to the prey abundance is due to increased oviposition or reproduction rather than adult aggregation. As a result of the numerical response of *Orius*, *T. palmi* populations are suppressed in home gardens which are rarely sprayed with insecticides. The occurrence of alternative prey of *Orius* also plays an important role in the naturally-occurring biological control of *T. palmi* because *Orius* can build up their population by consuming other thrips before the occurrence of *T. palmi* on field eggplant. Abiotic factors, such as typhoon and biotic factors, such as spider predation are suggested to reduce field populations of *Orius*. In greenhouses, *Orius* have often been used for the biological control of *Frankliniella occidentalis*, but the population dynamics of *Orius* are not fully understood. Factors influencing the population buildup and persistence of *Orius* in greenhouses are discussed.

20-055

CHARACTERISTICS OF PREDATION BY *ORIOS*Nagai K., E. Yano¹Okayama Prefectural Agricultural Experiment Station, San'yo-cho, Okayama, Japan. ¹Div. Entomol. National Institute of Agro-Environmental Sciences, Tsukuba, Ibaraki, Japan.

The predatory responses of *Orius* species to prey species and prey stages vary with species or biotypes of *Orius*. In order to use *Orius* in biological control or IPM, it is necessary to know predatory characteristics of *Orius* species against major insect pests on a crop.

Thrips, aphids and spider mites are common and often concurrent pests on many kinds of fruit vegetables. However, sufficient informations about predation by *Orius* are often lacking.

Thrips palmi is the most serious insect pest of eggplant in Japan. Japanese growers apply insecticides frequently to control thrips. *Orius sauteri* is the most dominant and abundant species in vegetable fields in Japan. Therefore, characteristics of predations of this species were studied to facilitate the biological control of *T. palmi* on eggplants.

O. sauteri fed on thrips, aphids, spider mites and other arthropods and attacked thrips most frequently on eggplants in open field. The predatory responses of *O. sauteri* to major insect pests, *T. palmi*, *Aphis gossypii* and *Tetranychus kanzawai*, were investigated under laboratory conditions. The results suggested that *O. sauteri* is an effective predator of *T. palmi* on eggplants in open fields.

In order to develop a simulation model for evaluating the biological control of *T. palmi* by *O. sauteri* in greenhouses, predatory parameters by this species were estimated. The total number fed in the nymphal stage of *O. sauteri* was 203 second instar larvae of *T. palmi* at 25 °C, and the functional responses of all stages of *O. sauteri* to larvae and adults of *T. palmi* were close to Holling's type II curve.

If invited speaker, indicate title of session and name(s) of organizer(s):
20S-5 *Orius* spp. and Other Hemipterans for Biological Control of Agricultural Pests. E. Yano, Y. Hirose (Japan)

20-056

POPULATION INTERACTION BETWEEN ORIUS AND THRIPS IN GREENHOUSES.

E.Yano, K. Nagai¹, P.J.M. Mols², H.J.W. van Roermund², J.C. van Lenteren²

National Institute of Agro-Environmental Sciences, Tsukuba, Ibaraki, Japan -1 Okayama Prefectural Agricultural Experiment Station, San'yo-cho, Okayama, Japan -2 Department of Entomology, Wageningen Agricultural University, Wageningen, The Netherlands

Orius spp. are mentioned as important predators of thrips, aphids and eggs of lepidopteran insects in the field. In Europe, *Orius* spp. are released for controlling *Frankliniella occidentalis* and *Thrips tabaci* in greenhouses. *Orius* spp. have shown to suppress *F. occidentalis* very quickly in greenhouses because both *Orius* spp. and the thrips concentrate on flowers. By contrast, *Thrips palmi*, the most serious thrips pest in Japan, is mainly found on leaves in greenhouse eggplants. An indigenous *Orius*, *O. sauteri*, is known as an effective predator against *T. palmi* on eggplants in the field. Therefore, use of this *Orius* on greenhouse eggplants is expected in Japan. A simulation model was developed to evaluate the biological control of *T. palmi* with *O. sauteri* on greenhouse eggplants based on a general simulation program "INSIM". The simulation results suggest the importance of early release and high initial density ratio of *O. sauteri* to *T. palmi*. Effects of cropping season and host plant on the performance of *O. sauteri* were also evaluated. *O. sauteri* seems to be effective in warm seasons. The biological control with this species is thought to be more difficult on cucumbers than on eggplants or sweet peppers.

20-058

USE OF TWO POLYPHAGOUS MIRID PREDATORS IN INOCULATIVE BIOLOGICAL CONTROL OF VEGETABLE PESTS

O. Alomar, C. Castañé, J. Riudavets, R. Gabarra, M. Goula¹ & R. Albajes²

Unitat d'Entomologia Aplicada, IRTA Centre de Cabrils, E-08348 Cabrils - 1 Departament de Biologia Animal, Facultat de Biologia, Universitat de Barcelona, Diagonal 645, 08028 Barcelona - 2 Àrea de Protecció de Conreus UdL-IRTA, Rovira Roure, 177, E-25006 Lleida, Spain

Macrolophus caliginosus Wagner and *Dicyphus tamaninii* Wagner (Heteroptera: Miridae) are two native generalist predators being successfully used for Greenhouse Whitefly (*Trialeurodes vaporariorum* Westwood) management in outdoor tomato crops in Catalonia, Spain. Both predators also colonize greenhouses and contribute to biological control. In this paper we examine the effectiveness of inoculative releases of *D. tamaninii* and *M. caliginosus* in controlling Greenhouse Whitefly and Western Flower Thrips (*Frankliniella occidentalis* Pergande) on tomato or cucumber field-cages and greenhouse trials with varying predator: prey ratios. The potential of these polyphagous predators for inoculative or augmentative biological control is emphasized.

20-057

Biological control of western flower thrips, *Frankliniella occidentalis* with *Orius* spp. in greenhouses

J.J. Fransen & P.M.J. Ramakers

Research Station for Floriculture and Glasshouse Vegetables, Aalsmeer & Naaldwijk, The Netherlands

Over the last ten to fifteen years western flower thrips (WFT) has developed as a severe pest on both greenhouse ornamentals and vegetables. Natural enemies affecting greenhouse populations of WFT include predatory mites (*Amblyseius* spp.) and bugs (*Orius* spp.), parasitoids (*Ceranisus* spp.) and insectpathogenic fungi (*Entomophthora* spp., *Verticillium lecanii*). *Orius* spp. prey on WFT belonging to the first, second and adult stage and may also feed on other insects as well as pollen. Besides, adults disperse well in the greenhouse. Several *Orius* spp. have been introduced in greenhouses, among others *O. majusculus*, *O. niger*, *O. laevigatus*, *O. albidipennis*, *O. tristicolor* and *O. insidiosus*. Some of these species were difficult to mass rear. Good results have been reported with *O. insidiosus* and *O. laevigatus* on sweet pepper, gerbera and chrysanthemum. In cucumber with pollen being absent, however, *O. majusculus* seems to do better, although this species from Northern Europe has shown to be more diapause sensitive than, for instance, *O. laevigatus* from Southern Europe. *Orius* spp. may show an ovipositional preference for certain positions on host plants. When given a choice *O. insidiosus* will avoid laying eggs on roses which indicates that besides pollen production also other host plant characteristics influence the effect of *Orius* releases. Due to its polyphagous nature also interactions with other natural enemies and pests may occur.

PHYLOGENY OF APHELINIDAE

James B. Woolley and Mohammad Hayat¹

Department of Entomology, Texas A&M University, College Station, Texas, USA 77843. 1- Department of Zoology, Aligarh Muslim University, Aligarh 202001, U.P., India.

A dataset consisting of 75 morphological characters was scored for some 56 taxa of Aphelinidae and several outgroups. All genera of Aphelinidae were included, including some undescribed genera known to the authors. All genera currently placed in Eriaporinae were included, at least initially, as were various problem taxa such as *Cales*. In cases in which more than one state of a character was known for a genus, the group was treated as two or more terminal taxa.

Characters were taken from all body regions and included both internal and external features. Character systems that are relatively new to aphelinid systematics include features of the head, mouthparts and internal skeleto musculature associated with the prepectus and mesofurca.

Parsimony analysis was performed using heuristic search algorithms in PAUP Version 4.0. Results are somewhat unstable, in part due to effects of various outgroups on character polarity. Uncertainty regarding relationships of Aphelinidae to other Chalcidoidea remains a serious problem. Coccophaginae including Prospaltellinae and Phycsinac is clearly monophyletic, based in part on conformation of the mesofurca and associated musculature. Aphelininae including Aphytinae is monophyletic based in part on presence of linea calva and epicoxal pads under fore coxae. Azotinae is probably part of the aphelinine lineage, as is *Eriaphytis*.

Results indicate that heteronomous host relationships are characteristic of a single lineage of Aphelinidae. Evolution of particular forms of heteronomous biology in Aphelinidae is examined in the context of phylogenetic relationships.

20-060

CYTOTAXONOMIC STUDIES ON SOME SPECIES OF *ENCARSIA* FÖRSTER AND OTHER APHELINIDAE

F. Baldanza

Dipartimento di Entomologia e Zoologia Agraria, Università di Napoli "Federico II", Portici, Italy

The present knowledge on the cytotaxonomy of Aphelinidae is outlined. A chromosome study has been carried out on 13 species of *Encarsia* Förster (*E. asterobemisiae* Viggiani et Mazzone, *E. lutea* -Masi-, *E. lahorensis* -Howard-, *E. leucaspidis* -Mercet-, *E. partenopea* Masi, *E. tricolor* Förster, *E. pergandiella* Howard, *E. aspidioticola* -Mercet-, *E. berlesei* -Howard-, *E. citrina* -Craw-, *E. formosa* Gahan, *E. meritoria* Gahan, *E. transvena* -Timberlake-) and the karyotypes have been reconstructed; centromeric index (C.I.) and relative length (R.L.) has been assessed. Moreover, preliminary studies on chromosome banding carried out for all the species, show that it is possible to distinguish between karyotypes with the same chromosome number and shape; the G-banding of *E. partenopea*, confirms the possibility to use this chromosome attribute to accurately identify pairs of homologues for advanced genetic studies, particularly in taxa lacking polythene chromosomes.

All the available data seem to show that in *Encarsia*, the karyotype evolution consists in a series of robertsonian centric and tandem fusion-fission rearrangements except in *E. lutea* and *E. asterobemisiae*. The data obtained on these two species lead to the conclusion that the chromosome sets of the *lutea* complex might have evolved by different mechanisms such as polyploidy or increasing in the content of heterochromatin, or both.

Once again the importance of karyological data in systematic studies is outlined.

20-061

FUNICULAR GLANDS IN APHELINIDAE AND THEIR SIGNIFICANCE

P. A. Pedata, G. Viggiani

Centro di Studio CNR sulle Tecniche di Lotta Biologica, Portici, Italia

The male antenna of a few aphelinids shows, on one or more funicular segments, peculiar cuticular modifications, previously retained "sensillar complexes".

The external features of several types of these structures, found in some species of *Encarsia* Förster, are illustrated.

An ultrastructural study on *Encarsia asterobemisiae* Viggiani et Mazzone and related species demonstrated the association of these presumed "sensillar complexes" with underlying integumentary glands.

According to preceding studies, these secretory elements play a fundamental role in courtship and mating behaviour.

The taxonomic importance of these structures is discussed.

20-062

ESTIMATING ATTACK RATES BY THE PARASITOID APHYTIS

W.W. Murdoch, S.L. Swarbrick

Department of Biological Sciences, University of California, Santa Barbara, CA USA

Aphytis melinus appears to be the major biological control agent of California red scale, a pest of citrus, in Southern California. We are developing a detailed individual-based population model of the interaction that requires independent estimates of per head attack rate by Aphytis in the field throughout the year. An added difficulty is that Aphytis is a host-feeding parasitoid that matures new eggs throughout its life if host meals are available.

This talk will describe a method we have developed and tested for obtaining these estimates. In the fall, when scale was most abundant, it appears that Aphytis was producing eggs and parasitizing hosts at the maximum temperature-dependent rate. This is not expected if it is assumed that Aphytis controlled the scale population at that time.

20-063

SWEET REWARDS: TROPHOBIOSIS AND NATURAL ENEMIES

M. Rose

Department of Entomology, Texas A&M University, College Station, TX U.S.A.

The so-called Argentine ant, *Iridomyrmex humilis* (Mayr), utilizes homopteran honeydew as a major food source. The woolly whitefly, *Aleurothrixus floccosus* (Maskell), an international pest of citrus, produces copious amounts of honeydew. On southern California citrus the trophobiotic relationship of these reunited exotic invaders affects the relative abundance of *A. floccosus* parasites. The roles and interactions of *I. humilis* and *A. floccosus*, and the imported parasites *Cales noacki* Howard, *Eretmocerus* Haldeman, and *Amitus spiniferus* Brethes, are discussed.

20-064

CANNIBALISM IN *APHYTIS*S. Ben-Shalom, Y. Rössler¹, D. Rosen

Department of Entomology, Faculty of Agriculture, The Hebrew University of Jerusalem, Rehovot, Israel - 1 The Israel Cohen Institute for Biological Control, Citrus Marketing Board of Israel, Bet-Dagan, Israel

Wasps of the genus *Aphytis* Howard (Hymenoptera: Aphelinidae) develop as primary, gregarious ectoparasitoids of armored scale insects (Homoptera: Diaspididae). We have studied the ecology of intra-specific competition among the developing larvae of a uniparental strain of *A. lingnanensis* Compere, reared on the oleander scale, *Aspidiotus nerii* Bouché. A clutch-size manipulation experiment was performed by transferring the parasitoid immature stages, at various densities, onto unparasitized hosts. Intra-specific competition increased as clutch size increased. Monitoring larval development on a daily basis indicated that the only density-dependent mortality factor was intra-specific predation (i.e., cannibalism). Lower rates of cannibalism were found in clutches where all individuals were sibs than in clutches composed of non-sibs. This suggested that sib-recognition occurred among the larval stages of *Aphytis*. Adult size was strongly influenced by the intensity of cannibalism; thus, non-sibs were larger than sibs. Female larvae exhibited a high degree of cannibalism toward males, causing a female-biased secondary sex ratio as rates of cannibalism increased.

20-066

DUAL ONTOGENY ON *ENCARSIA PORTERI* (MERCET) (HYMENOPTERA: APHELINIDAE) SPECIALLY RELATED TO PARASITISM OF LEPIDOPTERAN EGGS

E. A. LOBOS, A. E. DARCHUK

Department of Biology-Faculty of Agronomy-University of Santiago del Estero-Argentina.

In Argentina, *Encarsia porteri* (Mercet) is found in cotton crops, parasitizing *Bemisia tabaci* (Genn.) (Homoptera: Aleyrodidae), *Alabama argillacea* Hubner (cotton leafworm-CLW) and *Helicoverpa gelotopoeon* Dyar (cotton bollworm-CBW) (Lepidoptera: Noctuidae).

Laboratory studies were carried out (25 °C, HR 65-70%) to find out the biology of males of *E. porteri* and the preference of the non-copulated females for lepidopteran host.

In CLW eggs (n=42), the duration of the pre-adult instars of *E. porteri* was: eggs: 2.5; larvae I-III: 3.9 and male pupae: 7.7 days respectively. It took 14.33 (SD=1.04) days from parasitization to the emergence of adult. *E. porteri* females (n=10) parasitized an average of 19 (SD=14.86) eggs of *A. argillacea*. Aphelinids females (n=10) significantly prefer to parasitize eggs of CLW rather than of CBW (t_{0.5,9}). Percentages of parasitism were 28.12 and 3.75 % respectively. The rate parasitized eggs/contacted eggs was 0.49 for the CLW and 0.16 for the CBW.

Field studies (28° 5' S; 64° 10' O), were carried out during 1992/3 and 1993/94 in order to understand the seasonal parasitism of the oophagous found in cotton crops.

E. porteri is found from December though February. The proportion of parasitized eggs of *A. argillacea* the values of the proportions were 3% (n=1844) and 14 % (n=1319) respectively. For *H. gelotopoeon* (n=189 and n=425 respectively) the values of the proportions were 1% lower in both periods. All aphelinids emerged from parasitized eggs were male.

Among the eggs of CLW collected in 1993/94, there was one from which both a male of *E. porteri* and a female of *Trichogramma pretiosum* Riley. From another eight black eggs, which had signs of having been parasitized by *T. pretiosum*, aphelinids males emerged. Apparently, the high parasitism rate and the decrease in the density of host eggs determined conditions for both parasitoids to compete.

20-065

OVIPOSITION MECHANISMS IN THE WHITEFLY PARASITOID, *ENCARSIA* AND *ERETMOCERUS* (HYMENOPTERA: APHELINIDAE)

D. L. J. Quicke, D. Gerling

Department of Biology, Imperial College at Silwood Park, Great Britain - Department of Zoology, George S. Wise Faculty of Life Sciences, Tel Aviv University, Israel.

Species of the aphelinid genera *Encarsia* and *Eretmocerus* both parasitize whiteflies but their development is quite different, the former being endoparasitoids which develop from eggs laid within the host whereas the latter develops as 'pseudo' endoparasitoids from an egg laid external to (underneath) the host. We investigated the morphology of the ovipositors of these two taxa using scanning and transmission electron microscopy.

The apex of the dorsal ovipositor valve (gonapophyses of 9th abdominal segment) of the endoparasitic *Encarsia transvena* was found to be sharply pointed and well-sclerotized and therefore adapted for penetration through the host cuticle. In contrast, that of *Eretmocerus mundus* was atypical in that it formed a flat and apparently flexible pad that is likely to make penetration of the host cuticle unlikely. These and other features of the ovipositors are illustrated and described in detail.

20-067

PARTHENOGENESIS-INDUCING MICROORGANISMS IN *APHYTIS* AND OTHER APHELINIDSE. Zchori-Fein, Y. Gottlieb, R. T. Roush¹, J. H. Werren², D. Rosen

Department of Entomology, Faculty of Agriculture, The Hebrew University of Jerusalem, Rehovot, Israel - 1 Waite institute, Adelaide, Australia - 2 Department of biology, University of Rochester, Rochester N.Y, USA

In parasitic Hymenoptera, severe sex ratio distortion are sometimes associated with the presence of symbiotic microorganisms. Symbiont-induced uniparental reproduction has been reported from several families in the Chalcidoidea. About one fourth of all species of the aphelinid genus *Aphytis* exhibit thelytokous parthenogenesis. After antibiotic treatments successfully induced the production of male in uniparental lines of *Aphytis*, various aspects of the relationships between the wasps and their symbionts were studied: 1) The systematic status of the parthenogenesis-inducing microorganisms was determined by using two genes (16s rDNA and *ftsZ*) for the construction of a phylogenetic tree. 2) Electron microscopy as well as confocal microscopy were used to confirm the presence of microorganisms in uniparental lines of *Aphytis* and to follow the distribution pattern of the symbionts in the ovaries and eggs. The analyzed data assign the symbionts to the genus *Wolbachia* and show that *Wolbachia* from different *Aphytis* species are almost identical. Results suggest that *Wolbachia* move from nurse cell to developing oocytes. In freshly-laid eggs, the symbionts are concentrated in the posterior pole, and in later stages of embryogenesis they are found surrounding nuclei throughout the embryo.

20-068

POPULATION BIOLOGY AND BEHAVIOR OF *APHELINUS ASYCHIS* WALKER AND *APHELINUS VARIPES* (HYMENOPTERA: APHELINIDAE), MAJOR PARASITOIDS OF *DIURAPHIS NOXIA* (MORDVILKO) (HOMOPTERA: APHIDIDAE)

K. R. Hopper¹, K. Chen², D. Coutinot², A. Farias³, X. Fauvergue⁴, D. J. Kazmer¹, and N. Ramualde¹

¹ BIIR-ARS-USDA, Newark, Delaware, USA; ² EBCL-ARS-USDA, Montpellier, France; ³ Universidade Federal de Pernambuco, Recife, Brazil; ⁴ Université Claude Bernard Lyon I, Villeurbanne, France

We describe the distribution of *Aphelinus asychis* and *Aphelinus varipes* on *Diuraphis noxia* throughout Eurasia. We discuss the spatial and temporal dynamics of *D. noxia* parasitism in southern France. We present results on host defense behavior, parasitoid search, and genetics of host specificity to distinguish among hypotheses concerning the low number of *D. noxia* parasitized per colony. We summarize results on the mating-finding behavior and dispersal of *A. asychis* and present mathematical models of populations dynamics that incorporate these results. We discuss the implications of these models for establishment of introduced populations and describe field experiments to test these implications. We summarize results on the quantitative genetics of *A. asychis* fitness components which show no directional changes during long-term laboratory rearing but suggest that drift does occur. We compare fitness components for crosses within and between cultures derived from collections of *A. asychis* throughout Eurasia. These crosses show differences in fitness components within, but not among, cultures. The crosses revealed reproductive incompatibility among cultures from different geographic regions; which subsequent experiments showed was caused by lack of sperm transfer. We discuss the implications of our research for the design of biological control introductions.

APHELINID PARASITOIDS AS SUSTAINABLE BIOLOGICAL CONTROL AGENTS IN GREENHOUSES

J.C. van Lenteren

Laboratory of Entomology, Wageningen Agricultural University,
P.O. Box 8031, 6700 EH Wageningen, The Netherlands
email: joop.vanlenteren@medew.ento.wau.nl

Aphelinid parasitoids have been used for control of pests in greenhouses since the 1920s, but large scale application started only some 25 years ago. A success story is the biological control of greenhouse whitefly, *Trialeurodes vaporariorum*, with the aphelinid *Encarsia formosa*. Nowadays this parasitoid is applied on 5000 hectares of vegetable crops in most countries with a reasonable greenhouse industry. Weekly, more than 20 million individuals of *E. formosa* are mass reared and shipped to growers. About 10 years ago, another whitefly species, *Bemisia* sp., developed to pest status. Although *E. formosa* does attack *Bemisia*, it is not capable to reduce *Bemisia* numbers to the same very low levels as it does with greenhouse whitefly. Therefore, a search for more effective natural enemies for *Bemisia* was started. Several other aphelinid species are studied for control of scales and aphids. The following recent developments will be discussed concerning the role of aphelinids in greenhouse biological control:

1. status of commercial biological control with aphelinid parasitoids,
2. survey of aphelinid parasitoids under study,
3. use of preintroductory evaluation methods to select potentially promising aphelinid parasitoids,
4. quality control methods of mass reared aphelinid parasitoids,
5. the issue whether (partial) hyperparasitoids should be imported and released, and
6. the question if parasitoid biotypes studies are useful to identify suitable candidates for biological

20-069

POPULATION DYNAMICS OF THE ARROWHEAD SCALE, *UNASPIS YANONENSIS* (HOMOPTERA: DIASPIDIDAE) UNDER BIOLOGICAL CONTROL

M. Takagi, N. Sugiura

Faculty of Agriculture, Kyushu University, Fukuoka, Japan

The arrowhead scale, *Unaspis yanonensis* was one of the serious citrus pests in Japan before the introduction of the two parasitoids, *Aphytis yanonensis* and *Coccobius fulvus* from China. Population dynamics of *U. yanonensis* were studied from 1982 to 1995 at a citrus grove in Fukuoka, Japan. We released only *A. yanonensis* in June, 1982 at the grove and *C. fulvus* invaded from outside of the grove in 1989. The adult female density of *U. yanonensis* decreased rapidly after the release of *A. yanonensis*, which kept the density low level after that. The population density of *U. yanonensis* decreased to further low level after the invasion of *C. fulvus*. Seasonal changes of the host density and the percentage parasitism of the two parasitoids indicate that the two parasitoid perform as complementary natural enemies and both parasitoids contribute to maintain the pest population at lower level than single species introduction.

20-071

STEMBORER ECOLOGY

K M Harris

Research Associate, International Institute of Entomology, London, UK

The ecology of lepidopterous stemborers of cereal crops (wheat, rice, maize, sorghum, pearl millet, etc.) and sugarcane is briefly reviewed, with particular reference to the most important pest genera of Pyralidae (*Ostrinia* Hübner, *Chilo* Zincken, *Scirpophaga* Treitsche, *Diatraea* Guelding, *Eldana* Walker, *Coniesta* Hampson) and of Noctuidae (*Busseola* Thunberg, *Sesamia* Guenée). The stem-boring habit in Lepidoptera feeding on Poaceae [= Gramineae], Cyperaceae and Typhaceae has evolved polyphyletically over about 25 million years, since the late Tertiary. Pest interactions with cultivated crops and their precursors over the past 10,000 years are therefore comparatively recent. Current interactions of indigenous and non-indigenous stemborer genera with indigenous and non-indigenous host plants indicate dynamic elements that persist, especially through changes in geographical distribution and host range.

Good ecological information on stemborer species and complexes is necessary for effective planning of pest management strategies and is now available for most major species on their main crop hosts. There is however a continuing need for ecological research on stemborers on crops and on non-crop hosts (mostly grasses and sedges), including higher trophic interactions with natural enemies.

20-072

IMPACT OF ECOLOGY AND HOST PLANT SHIFTS OF *ELDANA SACCHARINA* WALKER (LEPIDOPTERA: PYRALIDAE) ON ITS BIOLOGICAL CONTROL IN GRAMINACEOUS CROPS

D.E. Conlong
South African Sugar Association Experiment Station, Mount Edgecombe, Kwazulu-Natal, South Africa

Biological control of *Eldana saccharina*, although considered one of the better control options in sugarcane and other graminaceous crops in Africa, has been difficult to implement. In addition to the very cryptic nature of *E. saccharina* in these crops, which protects it from a number of more conventional control measures such as pesticide applications, there are a number of other factors complicating establishment of biological control agents.

- It is indigenous to Africa, where it occurs in numerous wetland sedges and grasses. Classical biological control strategies therefore cannot be implemented.
- Even though it was described from sugarcane in Sierra Leone over 100 years ago, it is regarded as a recent invader of sugarcane in especially southern Africa. Here it first reached pest status for a period in 1939, and since 1970 has been of major concern to the South African sugar industry. It is thus unlikely that indigenous natural enemies have had time to colonise this "new" habitat.
- Previous workers have found very few natural enemies, especially parasitoids, in graminaceous crops. The impression has thus been created that *E. saccharina* has very few parasitoids. However, if successful natural enemies were present in the crops investigated, this borer would not be a pest. In addition, no work had been done to investigate the ecology and natural enemy complex of *E. saccharina* in its indigenous host plants. Studies of this nature could thus provide some pointers to its control in crop plants.

This paper discusses pest-host plant association, host plant shift, indigenous pest control and biological control concepts in the light of current knowledge.

SYSTEMATICS IN STEM BORER BIOCONTROL

A. Polaszek
International Institute of Entomology, London, U.K.

Past and current biocontrol programmes developed against cereal stem boring Lepidoptera have depended for their success on having a sound basis in natural enemy systematics. A great deal of confusion has been apparent in the past, and in many cases has been perpetuated for decades, compounding the effects of misidentifications or misunderstandings. Poor taxonomy can vastly increase the amount of work carried out by biocontrol and IPM practitioners, for example by the reintroduction of agents into areas where they are already present, though known by a different name, or as yet unidentified. Conversely, sound systematics is essential for biocontrol success, and often draws attention to hitherto untapped resources of new potential control agents. The past and current situations regarding stem borer natural enemies are reviewed with specific examples, and suggestions for future research, and in particular future collaboration between systematists and IPM/biocontrol practitioners are proposed.

20-076

BIOLOGICAL CONTROL OF STEM BORERS BY TACHINID FLIES, PAST AND FUTURE

F. D. Bennett

Crofton, Baldhoon Road, Laxey, Isle of Man

In the 80 years since the first attempts were made to introduce *Lixophaga diatraeae* Townsend from Cuba to Louisiana for the control of *Diatraea saccharalis* (Fabricius) tachinids have been introduced into fifty countries for the control of gramineous stem borers with varying degrees of success. In addition to classical biological control other strategies involving inoculative and inundative releases, mass production of tachinids on natural and factitious hosts, genetic improvement and amelioration of the microhabitat have been attempted. These as well as the status of current major programs are reviewed to determine the direction of future research and utilization of tachinids as control agents of stem borers.

20-078

USE OF *TRICHOGRAMMA*, ESPECIALLY AGAINST *OSTRINIA*

D.B. Orr

Department of Entomology, North Carolina State University, Raleigh,
NC 27695 USA

Trichogramma are the most widely augmented species of natural enemy worldwide. Strategies for implementation of *Trichogramma* use are also the most diverse of any augmented natural enemy. Production facilities have been adapted to fit into a variety of socioeconomic conditions. These range from outdoor labor-intensive insectaries that provide *Trichogramma* to local surrounding farms, to mechanized biofactories producing and marketing commercial products for input-intensive industrial farming. *Trichogramma* releases have also been adapted to fit into a wide variety of agricultural practices. Perhaps the best example of this is the implementation of *Trichogramma* for *Ostrinia* suppression in western Europe and North America. Implementation research efforts on *Ostrinia* suppression with *Trichogramma* in these regions have focussed recently on quality assurance, formulation, and delivery systems. These efforts have resulted in *Trichogramma* products which possess attributes similar to those of insecticides, such as long "shelf-life", long residual activity, and ability to be applied with conventional equipment.

20-077

PARASITIDS OF CONCEALED EGGS OF NOCTUID STEMBORERS AND THEIR POTENTIAL IN BIOLOGICAL CONTROL (HYMENOPTERA: SCELIONIDAE, TRICHOGRAMMATIDAE; LEPIDOPTERA: NOCTUIDAE)

F. Bin¹, E. Conti¹, R. Giacometti², S. Di Ferdinando¹

1 Istituto di Entomologia Agraria, Facolta' di Agraria, Universita' di Perugia, Perugia, Italy - 2 Dipartimento di Entomologia e Zoologia Agraria, Universita' di Napoli, Portici, Italy.

Several species of noctuid stemborers, mostly belonging to *Sesamia*, lay their egg masses between the leaf sheath and the stem of cultivated and wild Graminae. The egg masses in such concealed, or somewhat exposed, oviposition sites are directly attacked by trichogrammatids, which have a negligible impact, and by scelionids belonging to the genus *Telenomus*, which may exert an effective natural control.

Telenomus species are of two different groups according to their morphological adaptation and attack strategy. The "crawlers" (e.g. *T. busseolae*), which have a flattened body, reach the eggs by crawling between leaf blade and stem, and the "drillers" (e.g. *T. cirphivorus*), which are not flattened, lay their eggs by drilling with the ovipositor through the leaf sheath. Their host associations and effectiveness are reviewed and discussed. Rearing techniques of *S. nonagrioides* and *T. busseolae* and preliminary results on host recognition cues are described. Taxonomic revision for undescribed reared "drillers" and for described species from unknown hosts and possibly belonging to "crawlers", is suggested.

BIOLOGICAL CONTROL EFFORTS AGAINST THE CEREAL STEM BORERS, *BUSSEOLA FUSCA* AND *CHILO PARTELLUS* IN SOUTH AFRICA

Rami Kfir

Plant Protection Research Institute, Private Bag X134, Pretoria 0001, South Africa

The most important pests of cereal crops in South Africa are the stem borers, *Busseola fusca* (Fuller) (Lep. : Noctuidae) which is indigenous, and *Chilo partellus* (Swinhoe) (Lep. : Pyralidae) which invaded Africa from India.

In South Africa 18 indigenous parasitoids were recorded from *B. fusca* and 13 parasitoids from *C. partellus*. These parasitoids reduce pest populations but are not able to prevent economic damage.

During the last 20 years several attempts have been made to augment the fauna of the local parasitoids of stem borers by introductions of exotic parasitoids. The following parasitoids were introduced: *Allorhogas pyralophagus* (Marsh) (Braconidae), *Cotesia flavipes* (Cameron) and *C. chilonis* (Munakata) (Braconidae), *Descampsina sesamiae* Mensil (Tachinidae), *Mallochia pyralidis* Wharton (Ichneumonidae), *Meloboris sinicus* (Holmgren) (Ichneumonidae), *Metagonistylum minense* Townsend (Tachinidae), *Paratheresia claripalpis* Van der Wulp (Tachinidae), *Sturmiopsis inferens* Townsend (Tachinidae), *Tetrastichus howardi* (Olliff) (Eulophidae), *Trichogramma chilonis* Ishii and *T. ostrinia* Pang & Chen (Trichogrammatidae), and *Xanthopimpla stemmator* Thunberg (Ichneumonidae).

Several recoveries of introduced parasitoids have been made from field collected stem borers but the impact on the local pest populations was negligible.

20-082

ENVIRONMENTAL ISSUES CONCERNING THE IMPORTATION OF NON-INDIGENOUS BIOCONTROL AGENTSF.G. Howarth

Department of Natural Sciences, Bishop Museum, Honolulu, HI, USA

The importation and release of non-indigenous organisms to control pest populations continues to be promoted as environmentally safe; however, accumulating evidence from past and current projects raises serious concerns. Introduced biocontrol agents have been implicated in the extinction of numerous nontarget species, disrupted native ecosystems, and affected human welfare. Of greatest concern is species extinctions, especially on islands (including numerous species of land snails, insects, birds, and reptiles), but severe negative impacts also occur in continental areas. Many effects were discovered serendipitously by persons conducting fieldwork at the right time and place, thus many impacts escaped notice and remain undocumented.

The technology is as highly unnatural and anthropocentric as is the use of chemical pesticides and should be recognized as artificial rather than natural biocontrol. Persons releasing organisms beyond their natural range undertake a grave responsibility; once released these agents are pervasive (i.e., able to disperse far beyond the target system), permanent (i.e., able to multiply and evolve in perpetuity), injurious (i.e., able to harm nontarget organisms), and insidious (i.e., able to affect ecosystems, sometimes in profound ways). Long-term ecological studies are needed on both the efficacy and environmental impacts of biocontrol introductions to make applied ecology more predictive and to produce more appropriate protocols governing proposed introductions. Given the risks, more open and comprehensive public oversight and regulation of all proposals to introduce and release non-indigenous organisms is required.

20-081

RELEASES OF EXOTIC PARASITIDS AGAINST EXOTIC AND NATIVE STEMBORERS IN AFRICA AND NEIGHBORING INDIAN OCEAN ISLANDSW. A. Overholt

International Centre of Insect Physiology and Ecology (ICLPE), P.O. Box 30772, Nairobi, Kenya.

There have been many attempts over the past fifty years to suppress populations of exotic and native lepidopteran stem borers in Africa and neighboring Indian Ocean Islands through the introduction of exotic parasitoids. Several parasitoids have been successfully established in the Mascarene Islands and in Madagascar, but there were no successes reported from mainland Africa until very recently when the exotic parasitoid, *Cotesia flavipes* Cameron, was introduced into Kenya. All the parasitoids that have established on the Indian Ocean Islands and in Kenya are thought to represent old parasitoid/host associations, and *Cotesia* spp. represent a disproportionate share of the establishments. Possible factors which have influenced the establishment of exotic parasitoids and implications for future biological control programmes are discussed.

20-083

ENTOMOLOGIST AS PIVOTAL HONEST BROKER IN THE BIOCONTROL-INSECT CONSERVATION DEBATEM.J. Samways

Invertebrate Conservation Research Centre, Department of Zoology and Entomology, University of Natal, Pietermaritzburg, South Africa.

Population decline, range shrinkage, range lacunae and species extinction have characterized the increasing intensity of landscape fragmentation. Biocontrol practitioners have both exacerbated and slowed this attrition of biodiversity. Conservationists, in contrast, unequivocally aim to maintain biodiversity, yet have made few positive suggestions which rationalize species preservation and biotic pest control. A polarized and, at times, unscientific, debate has developed.

Have we really weighed the relative risks and advantages of biocontrol, from the view that it is inevitably going to be more widely practised? It seems as though a graded risk strategy is our only option. If so, what form should it take? A way forward is suggested, with special reference to South African examples.

HARVESTING SAFELY FROM BIODIVERSITY: NATURAL ENEMIES AS SUSTAINABLE AND ENVIRONMENTALLY FRIENDLY SOLUTIONS FOR PEST CONTROL

J.C. van Lenteren

Laboratory of Entomology, Wageningen Agricultural University,
P.O. Box 8031, 6700 EH Wageningen, The Netherlands
email: joop.vanlenteren@medew.ento.wau.nl

A study of the European biological control literature leads to the conclusion that importation of arthropods for biological control of pest arthropods has not led to unwanted side-effects. Current pest control policies in many European countries support or stimulate biological control, and natural enemy imports increased during the past three decades. At the same time development of rules takes place, making import and release of non-indigenous organisms very difficult. It is of great priority to find a balance between reasonable regulation of importation of new candidates for biological control and the possibility to develop sustainable, environmentally safe pest control.

Use of non-indigenous micro-organisms for biocontrol is covered by the national registration procedure of each European country. For macro-organisms, European countries have very different criteria to allow importation and release. They range from no criteria at all to rather strict criteria including information on potential environmental impacts. Harmonization for importation of non-indigenous organisms is under discussion within the EU, and there are efforts to include elements of the FAO Code of Conduct for the Importation and Release of Biological Control Agents into the EU regulation. Regulation of importation of natural enemies may be needed, but such ruling should preferably be developed by scientist and biocontrol practitioners, not by administrators. Very strict regulation procedures for biocontrol agents will result in more damage for the environment because of the continued use of chemical pest control and demotivates those with an honest approach for developing environmentally friendlier alternatives.

RESPONSE OF 3 HYMENOPTERAN PARASITOIDS INTRODUCED FOR FRUIT FLY CONTROL TO A NON-TARGET TEPHRITID, *PROCECIDOCHARES ALANAE* (DIPTERA: TEPHRITIDAE): IMPLICATIONS FOR BIOLOGICAL CONTROL IN HAWAII

M. F. Purcell, J. J. Duan¹, and R. H. Messing¹

U.S. Department of Agriculture-Agricultural Research Service, Hilo, HI
USA -1 University of Hawaii, Department of Entomology, Kauai Research Center, Kapaa, HI USA

The response of 3 larval-pupal parasitoids, *Diachasmimorpha longicaudata* (Ashmead), *D. tryoni* (Cameron), and *Tetrastichus giffardianus* Silvestri to the pamakani gall fly, *Procecidochares alanae* L. was determined in the laboratory. We also observed responses of these parasitoids to their normal rearing hosts, *Bactrocera dorsalis* (Hendel), and *Ceratitidis capitata* (Weidemann). *D. tryoni* landed on pamakani galls or on dishes containing *P. alanae* larvae as frequently as on dishes containing *C. capitata*. In contrast, *D. longicaudata* only rarely landed on the galls. *D. tryoni* and *D. longicaudata* rarely oviposited in galls (< 1% of observations). *D. longicaudata* probed in *P. alanae* larvae in the dishes as frequently as in *B. dorsalis* larvae, but no parasitoid offspring were observed. Ovipositional probes of *D. tryoni* were more frequently observed in *C. capitata* than all other substrates. No *D. tryoni* developed in gall fly larvae. *T. giffardianus* landed on pamakani galls and *P. alanae* larvae as often as on *B. dorsalis*. However, no *T. giffardianus* were observed entering galls with artificially opened windows. A 1 year field survey was done to determine the abundance of parasitoids of *P. alanae*. None of the parasitoids recovered were species introduced for control of the pest tephritids in Hawaii. The following 4 species were recovered: *Eupehmus cushmani* (Crawford), *Eurytoma tephritidis* Fullaway, an unidentified torymid and pteromalid. We discuss the implications of our results for future augmentative or classical biological control studies.

20-085

IMPLICATIONS OF NON-TARGET EFFECTS OF INTRODUCED BIOLOGICAL CONTROL AGENTS PARTICULARLY WITH RESPECT TO BENEFICIAL SPECIES

B.I.P. Barratt, C.M. Ferguson, A.A. Evans

AgResearch, Invermay Agricultural Centre, Private Bag 50034, Mosgiel,
New Zealand

A New Zealand research programme has been initiated to evaluate the effects of entomophagous biological control introductions on non-target species, and to improve quarantine protocols for regulatory authorities to implement prior to approving new introductions. As a model, methods are being developed to assess and monitor the impact on non-target organisms of *Microctonus aethiopoides* Loan and *M. hyperodae* Loan (Hymenoptera: Braconidae), parasitoids already released to control the adult stage of the introduced forage pests *Sitona discoideus* Gyllenhal and *Listronotus bonariensis* (Kuschel) (Coleoptera: Curculionidae) respectively. Field surveys have shown that many species of taxonomically related native weevils occur in mixed populations with the target hosts. Laboratory host range tests have been carried out on some of these species showing that *M. aethiopoides* achieved higher levels of parasitism in native species than *M. hyperodae*, indicating that it may be a more polyphagous parasitoid species. Monitoring field populations of non-target weevil species has so far supported this finding, with 13 non-target species having been found parasitised by *M. aethiopoides*, and one by *M. hyperodae*.

Studies have shown that one of the unintended hosts of *M. aethiopoides* is *Rhinocyllus conicus* (Froehlich), a weed biological control agent introduced to control nodding thistle. Current research is evaluating the effect of parasitism on *R. conicus* survival and fecundity. While *R. conicus* was exposed to *M. aethiopoides* in limited host range tests before release in 1982, no parasitism was detected. This raises the question of the design of adequate laboratory tests, and also the potential for parasitoids to become 'conditioned' to alternative non-target hosts.

20-087

ETHICAL STANDARDS AND CONCERNS OF INTERNATIONAL BIOLOGICAL CONTROL

J.A. Lockwood

Department of Plant, Soil, and Insect Sciences, University of Wyoming, Laramie, WY

A system of environmental ethics recently developed by Lawrence Johnson is integrated with standards of professional ethics to analyze the moral implications of biological control technologies. Entities are morally relevant when they possess wellbeing interests (i.e., functions or processes that can be better or worse in so far as the entity is concerned) and species/ecosystems are morally relevant because they are not simply aggregates of individuals, so their processes, properties and wellbeing interests are not reducible to the sum of their individual members. Following Johnson's thesis, species and ecosystems have morally relevant interests in surviving and maintaining themselves as integrated wholes with particular self-identities. This theoretical structure gives rise to a number of ethical criteria that are particularly relevant to practitioners of biological control, who are professionally obligated to recognize these constraints. These criteria apply to the ecosystem (the extent to which it is large, native, unique, and integrated) and to the action being considered (the extent to which it is novel, omnipresent, monitored, reversible, and necessary). In these terms, it is evident that not all biological control efforts are ethically defensible. In general terms, natural biological control is most desirable, followed by augmentative strategies, classical approaches, and finally neoclassical biological control. Specific cases are examined to illustrate the ethical concerns. Finally, it is argued that formalized restrictions of biological control are necessary, given the ethical obligations of the scientific community and the unique properties of biological control technologies.

20-088

ENSURING THE QUALITY, SAFETY AND FAIRNESS OF
INTERNATIONAL BIOLOGICAL CONTROL

Jeff Waage

International Institute of Biological Control,
CAB INTERNATIONAL, Ascot, Berks, UK

Alien invasive species are a growing problem worldwide: increased trade has accelerated the appearance of alien pests, traditional threats to agriculture are intensified by the potential to exploit alien pests as non-tariff trade barriers, and the importance of alien species as risks to biodiversity conservation is generating growing concern in the environmental community. Classical biological control (CBC) has the potential to contribute to the management of these problems. However, as concerned stakeholders in CBC expand from a traditional, small scientific community in a few, developed countries to include new countries, non-scientists and the public at large, there is a need for greater awareness and understanding of CBC and for consensus on procedures for its safe and fair implementation. Some recent international agreements suggest how this can begin, but there is more to be done.

20-089

NON-INDIGENOUS SPECIES AND BIOLOGICAL
CONTROL AND BIOLOGICAL AND REGULATORY
ISSUES, A CALIFORNIA PERSPECTIVE

R. F. Luck

Department of Entomology, University of California
Riverside CA USA

California is a microcosm of most of the issues and concerns involved in the introduction of non-indigenous organism, their regulation and their management. Unlike the old world, the period over which California's landscape and economic interests have been affected by non-indigenous organisms has been brief. It began with the establishment of the Jesuit Missions along California's coast in the late 1700s and remains largely unabated today because of the global economy and international trade.

Initially, the regulatory concerns about non-indigenous organisms arose because of agricultural interests. Other regulations have followed, both State and Federal, and they have sought to prevent the introduction of a variety of organisms, largely based on special economic interests. More recently, environmental concerns have entered the regulatory arena. Generally, the strategy of regulation has focused on developing specific lists of taxa that cannot be imported or released, rather than on a process of evaluating the risk or benefit of an introduction. This has lead to a hodgepodge of poorly coordinated regulations that have evolved by accretion. The current approach has been of limited effectiveness. Its reappraisal is sorely needed. These issues affect biological control's practices and procedures. We have a professional and ethical obligation not to exacerbate the problem of non-indigenous organisms.

20-090

INBREEDING EFFECTS ON THE DEVELOPMENT AND REPRODUCTION OF THE PREDATOR *PODISUS MACULIVENTRIS* (SAY) (HETEROPTERA: PENTATOMIDAE)

P. De Clercq & D. Degheele

Laboratory of Agrozoology, Faculty of Agricultural & Applied Biological Sciences, University of Gent, Belgium

The predatory pentatomid *Podisus maculiventris* (Say) has been recognized for its potential as a biocontrol agent of various lepidopterous and coleopterous crop pests. The current study focusses on the effects of inbreeding in the laboratory culturing of this beneficial insect.

Several developmental and reproductive parameters were measured throughout 15 generations of laboratory rearing to compare the quality of a reference population with that of two inbred populations. The latter were started from a small number of sister-brother founders and were subsequently kept at low population size. Predators in all colonies received caterpillars of the greater wax moth, *Galleria mellonella* L., and of the beet armyworm, *Spodoptera exigua* (Hübner), as food. Developmental and reproductive traits did not vary dramatically between the reference and inbreeding treatments. Nonetheless, weight and hatching of eggs, developmental rate and survival of nymphs, and total fecundity of females were consistently higher in the reference population than in both inbred populations. Weight and size of adults in the reference population, however, were intermediate between those of adults in the two inbred populations. No significant relationship between weight or size of female adults and their total fecundity could be established in laboratory-reared *P. maculiventris*.

20-092

ACCEPTANCE AND SUITABILITY OF UV-IRRADIATED *HELICOVERPA ARMIGERA* (HÜBNER) EGGS FOR *TRICHOGRAMMA CHILONIS* ISHII

J. Romeis, T. G. Shanower, C. P. W. Zebitz¹

Crop Protection Division, International Crops Research Institute for the Semi-Arid Tropics (ICRISAT), Patancheru, India - ¹ Institut für Phytomedizin, Universität Hohenheim, Germany

Helicoverpa armigera (Hübner) eggs were irradiated with UV-light. Egg mortality increased with duration of exposure to the UV-light source; 98% of eggs were killed with approximately 50 min exposure. Eggs were treated for 60 or 90 minutes and offered to *Trichogramma chilonis* Ishii females together with control eggs. Irradiated eggs were as readily accepted as untreated eggs. While clutch size and sex ratio of the progeny were not affected by the treatment, mortality of the developing parasitoid was higher in UV-irradiated eggs.

The different parasitization phases of *T. chilonis* females were observed on the first egg accepted on irradiated and untreated eggs in a no choice test. Drumming, oviposition and total time spent per host showed no difference but drilling time was significantly shorter on irradiated eggs. It seems, that morphological changes in the egg chorion have occurred during the treatment. These changes could be responsible for the higher parasitoid mortality in irradiated eggs, as the chorion regulates the water and gas exchange between egg and environment.

20-091

REARING THE GYPSY MOTH PREDATOR, *CALOSOMA SYCOPHANTA* L. ON AN ARTIFICIAL DIET (LEPIDOPTERA: LYMANTRIIDAE - COLEOPTERA: CARABIDAE),

Ronald M. Weseloh

Department of Entomology, Connecticut Agricultural Experiment Station, 123 Huntington Street, New Haven, Connecticut, USA 06504

Calosoma sycophanta L. is an important specialist predator of the gypsy moth in North America. It has been released in areas of the United States that gypsy moths have recently invaded, and there is interest in making further releases. Until recently, it has been necessary to rear the beetle on gypsy moths supplied by personnel at the US Department of Agriculture APHIS Methods Development Laboratory in Massachusetts, USA. An artificial diet would make rearing the beetles more economical. A diet for larval beetles has been developed, consisting of ground beef liver and chicken. Larvae can be reared from egg to adult on this diet, and the characteristics of the resulting adults compare favorably to beetles reared on gypsy moth pupae. An adult diet is also being developed because adult beetles must feed heavily on gypsy moth larvae in order to reproduce.

20-093

IN VITRO CULTURE OF THE PUPAL PARASITOID *BRACHYMERIA INTERMEDIA* (NEES) (HYMENOPTERA: CHALCIDIDAE)

M.L. Dindo, R. Farneti

Istituto di Entomologia "Guido Grandi", Università degli Studi di Bologna, Italy

Brachymeria intermedia, a polyphagous solitary endoparasitoid of lepidopterous pupae, was reared from the egg to adult stage on artificial media based on commercial veal homogenate for babies (Gerber®) integrated with chicken egg yolk, yeast extract, wheat germ and 10% extract of *Galleria mellonella* L. pupae. The mean adult yield was of about 61%.

Complete parasitoid development was obtained also on diets devoid of host material, i.e. containing only veal homogenate, egg yolk, yeast extract and wheat germ. Adult yields were, however, quite low (22.5%).

The adults appeared normal and were fecund.

20-094

ADVANCES ON *IN VITRO* REARING *TRICHOGRAMMA* SPECIES IN BRAZIL

J.R.P. Parra & F.L. C nsoli

Departamento de Entomologia, Escola Superior de Agricultura Luiz de Queiroz, Universidade de S o Paulo, Piracicaba, Brasil.

Research related to *in vitro* rearing of egg parasitoids in Brazil was initiated in 1990 with the first report in Latin America of the rearing of *Trichogramma pretiosum* on an artificial diet. Although the complete development on a diet composed of hemolymph of *Helicoverpa zea* was obtained, the survivorship and percentage of normal adults were very poor. Mold and/or bacteria contamination were also a limitant factor. In 1993, the addition of bovine fetal serum to this diet allowed the full development of *T. galloi* for the first time. Successive studies with *T. pretiosum* and *T. galloi* showed that both parasitoids differ in their nutritional requirements. The basic medium was composed of larval hemolymph of *H. zea*, egg-yolk, bovine fetal serum, and streptomycine. However, inclusion of egg-juice from *Heliothis virescens* increased the survivorship and adult normalcy of *T. pretiosum*, but not of *T. galloi*. Larval hemolymph of *H. zea* was preferred instead of *Bombyx mori* and pupal holotissues of *Diatraea saccharalis*, *Anticarsia gemmatilis* and *B. mori* because of the best results with the first one. Use of larval hemolymph of *H. zea* resulted in 50.89% and 26.10% of adult emergence for *T. pretiosum* and *T. galloi*, respectively, with a high percentage of normal adults. Wing deformities and an oversized abdome were the most common abnormalities. No deformities were observed on the genital apparatus. Both *in vitro*-reared parasitoids had a reduced parasitism capacity and longevity compared to the *in vivo*-reared ones. Studies on the parasitism behavior, chorionic ultrastructure of the hosts and ovipositional stimulants have been conducted to support the development of an artificial egg using plastic membranes.

20-096

STIMULANTS FOR IMPROVING *IN VITRO* REARING OF *TRICHOGRAMMA* SPP. (HYMENOPTERA: TRICHOGRAMMATIDAE) WITH ARTIFICIAL MEDIA WITHOUT INSECT HEMOLYMPHW.H. Liu¹, S.C. Han¹, Q.X. Chen¹, S. Grenier²¹ Guangdong Entomological Institute, Guangzhou, China² Laboratoire de Biologie Appliqu e, LA INRA, INSALyon, Villeurbanne, France.

Great progress has been made recently in research on *in vitro* rearing of *Trichogramma* spp. in China, France, etc. But, the insect hemolymph, as a main component of the artificial medium, is difficult to obtain in the countries other than China. It is very urgent to solve the problem of artificial diets without insect hemolymph. To improve the oviposition is the most important problem during *in vitro* rearing of *Trichogramma* spp. without insect hemolymph. In this paper, several kinds of chemicals were selected as ovipositional stimulants, among them the polyvinyl alcohol is the most effective and economical one which can be used for increasing the efficiency in oviposition of *Trichogramma brassicae* and *Trichogramma dendrolimi* in artificial eggs. The parasitism was 100%, the average number of trichogrammatid eggs in a capsule was 259.6 ± 97.5 (max. 456, min. 77) and 351.0 ± 98.6 (max. 566, min. 233) respectively. In the same conditions, control (non stimulant) was 27.5 ± 34.0 and 181.9 ± 43.2 , respectively.

20-095

DEVELOPMENT OF A UTILITARIAN, ARTIFICIAL CULTURE MEDIUM AND PRESENTATION SYSTEM SUITABLE FOR REARING MULTIPLE INSECT PREDATORS AND PARASITOIDS

P. GREANY

USDA Agricultural Research Service, Insect Attractants, Behavior & Basic Biology Research Laboratory, Gainesville, FL USA

The poster describes an inexpensive artificial culture medium free of any insect components as well as the production of a simple encapsulation/presentation system. The medium has supported the growth and development of several species of insect predators and parasitoids. Predators that have been successfully reared from egg-adult include several hemipterans (e.g., *Geocoris punctipes*, *Podisus maculiventris*, *Perillus bioculatus*, *Lyctocoris campestris*, and *Xylocoris flavipes*), and coleopterans (e.g., *Calosoma sycophanta* and *Coleomegilla maculata*). Two hymenopterous ectoparasitoids of noctuid pupae also have been successfully reared on the medium (*Diapetimorpha introita* and *Cryptus albitarsus*).

Encapsulation systems for the medium are described, along with optimization of procedures for terminal sterilization of the encapsulated units.

Results on growth, development, fecundity, and host/prey searching behavior of predators and parasitoids reared on the medium are described in accompanying presentations by other authors in the same session.

20-097

NUTRITIONAL STUDIES ON LARVAL DEVELOPMENT OF AN APHIDOPHAGOUS COCCINELLID, *HARMONIA AXYRIDIS* PALLAS — CHEMICALLY DEFINED DIET AND ACTIVE INGREDIENT IN DRONE HONEYBEE POWDER. —K. Nijima, T. Iwasa¹ and M. MatsukaLaboratory of Entomology, Faculty of Agriculture, Tamagawa University, Machida, Tokyo, Japan. ¹ Advanced Technology Laboratory, Kubota Corporation Ryugasaki, Ibaraki, Japan

Chemically defined diets (CDs), which is good to rear aphidophagous lacewings, consisting of amino acids, minerals, vitamins, sugar and cholesterol were tried to rear larvae of *H. axyridis*. These diets succeeded in their rearing until the 3rd instar but larvae never developed to the 4th instar on these CDs. Although many combinations of components and addition of some substances known to be effective for other insects were tried, no notable improvement was resulted. Consequently, these CDs lack some important factor(s) for *H. axyridis* growth. Drone honey bee brood powder (DP) is known to be the useful diet for many species of aphidophagous coccinellids. A water soluble fraction from defatted DP was effective on the larval development when it was added to the CDs at the ratio of 5% and 1st instar larvae developed to adults on this diet. The effective factor(s) was found to be substance(s) with low molecular weight (M.W. <10,000). In order to find active ingredients, this fraction was further fractionated and rearing tests were carried out using the fortified CD. This fraction was divided into four fractions by gel filtration and the subdivided fractions were also effective with some deterioration. The nature and role of these active ingredients were estimated.

20-098

FACTORS INVOLVED IN IN VITRO REARING *MELITTOBIA DIGITATA*M. Cooperband, P. Fanti¹, S.B. Vinson, R. W. Matthews²

Department of Entomology, Texas A&M University, College Station, TX USA
⁻¹ Present address: Dipartimento di Biologia, Difesa e Biotecnologie Agro-Forestali, Università della Basilicata, Potenza, Italy. ⁻² Department of Entomology, University of Georgia, Athens, GA USA.

The ectoparasitoid *Melittobia digitata* (Hymenoptera: Eulophidae) can be reared in the laboratory using artificial media free of insect tissue. There are two other factors important to rearing. One is obtaining oviposition on the artificial host containing the diet and the other is providing a suitable membrane to allow access to the media. We evaluated several membranes which provide access to the food while reducing contamination of the media by the parasitoids. Oviposition onto the artificial host has been obtained and some of the factors that influence the female's response are discussed.

20-099

A SUBSTRATE FOR MEASURING FECUNDITY ON MIRID BUGS

N. Agustí, J. Riudavets, C. Castañé

IRTA - Unitat d'Entomologia Aplicada, Carretera de Cabrils s/n, 08348 Cabrils (Barcelona) Spain

Mirid bugs are polyphagous predators used in biological control of greenhouse pests, including whiteflies and thrips. Routine test of fecundity in mass reared predators has to be done in order to check their quality as beneficials. Mirid bug eggs are difficult to see since they are completely inserted into the plant veins, petioles and stems. As their hosts are hairy plants, the difficult is even greater. Here we report on an easy way for measuring fecundity of mirid bugs. The oviposition substrate is a tobacco, tomato or cucumber leaf, with their main veins removed, placed on top of a thin agar layer (<4 mm). Bugs are fed with *Ephestia kuehniella* eggs. Mirid bug females oviposit in the leaf tissue and the whole egg is visible from the bottom of the cage, as cage and agar are transparent. Mean fecundity in leaf agar cages was not significantly different from fecundity on plant for the three plant species tested.

20-100

IN VITRO REARING OF *OOENCYRTUS KUVANAE* H. (HYMENOPTERA : ENCYRTIDAE) AND ITS OVIPOSITION BEHAVIOR

H. P. Lee, K. S. Lee, D. Y. Son

Department of Applied Biology, Dongguk University, Seoul 100-715, KOREA

In insectary condition (Temp. 27 ± 1 °C, RH $70 \pm 5\%$, L:D 16:8), *in vitro* rearing of *Ooencyrtus kuvanae*, parasitoid for Gypsy moth egg successfully achieved on artificial egg medium which used for *Trichogramma* sp..

For a effective inducing of the wasp's host acceptance on artificial egg bag-form, the kairomone of Gypsy moth egg extracted with ethanol treated on the surface of bag-form. The kairomone treated egg bag-form showed 5 times as high parasitism as untreated artificial egg bag-form, otherwise large number of females (40 females per artificial egg bag-form) were required to get above 90% parasitism for the one day exposure.

Adult female wasp reared from *in vitro* showed the greatest oviposition activities at 7 to 8 days after emergence. The period from egg to adult emergence were 15 ± 2 days and 10 ± 1 days for larval period, respectively. Most of the wasp were emerged in 15th to 16th day after oviposition and larval size of all instar were likely to be larger than those reared *in vivo*.

The first generation of wasp reared *in vitro* showed no difference in parasitism on natural eggs compared with the wasp reared *in vivo*.

20-101

A METHOD FOR MASS-REARING OF SPECIES *PODISUS MACULIVENTRIS* (SAY) (HETEROPTERA : PENTATOMIDAE)T. MANOLE, M. IAMANDEI¹

Department of Entomology, Research Institute for Plant Protection, Bucharest, Romania-¹Department of Entomology, Research Institute for Plant Protection, Bucharest, Romania

The researches carried out in the period '90-'94 had allowed of the mass-rearing, for the first time in Romania, of the predator species *Podisus maculiventris* (Say).

In the paper the results concerning the feeding behaviour, the duration of larval development, the female fecundity, the eggs fertility, the adults longevity and the active period of female under controlled conditions are presented.

20-102

The species of *Trichogramma* Westwood in Iran

E. Ebrahimi

Plant Pests & Diseases Research Institute, P.O.Box 1454/19395 Tehran-Iran

Nine species of *Trichogramma* have been collected from different parts of Iran on various lepidopterous eggs. These species and their hosts are as follows:

Trichogramma evanescens Westwood on eggs of *Cydia pomonella* and *Chilo suppressalis*; *T. rhenana* Voegle & Russo on eggs of *Naranga aenescens*; *T. embryophagum* Hart. on eggs of *Archips rosanus*, *Cydia pomonella*, *Ocnerogya amanda* and *Spectrobates ceratoniae*; *T. cacoeciae* Marchal on eggs of *Cydia pomonella* and *Spectrobates ceratoniae*; *T. maidis* P.V. on eggs of *Chilo suppressalis* and *Ostrinia nubilalis*; *T. cordubensis* Vargas & Cabello on eggs of *Chilo suppressalis* and *Ostrinia nubilalis*; *T. semblidis* Auriv. on eggs of *Sepedon spegea*; *T. brassicae* Bezdenko on eggs of *Chilo suppressalis*; *T. pinto* Voegle, host unknown. Investigations are now being carried out on electrophoretic analysis of species and strains.

20-104

VARIATIONS IN PINE PROCESSIONARY CATERPILLAR EGG PARASITISM PRODUCED BY AUGMENTATION WITH LABORATORY REARED *OOENCYRTUS PITYOCAMPAE* (MERCET)R. Tiberi⁽¹⁾, T. Niccoli⁽¹⁾, A. Niccoli⁽²⁾

⁽¹⁾ Istituto di Patologia e Zoologia forestale e agraria, Università di Firenze, Italy - ⁽²⁾ Istituto Sperimentale per la Zoologia Agraria, Firenze, Italy

In July 1993, a biological control trial was carried out to control the Pine Processionary Caterpillar, *Thaumetopoea pityocampa* (Denis et Schiffmüller) through the use of one of its egg parasitoids, *Ooencyrtus pityocampae* (Mercet), which was reared in the laboratory on *Nezara viridula* (L.) (Rhynchota, Pentatomidae) eggs. More than 26,000 individuals of the parasitoid were released in 7 different times over a period of six weeks into a pine stand of the *nigra* group in central Italy (Tuscany), in order to cover the whole flight period of the pine processionary moth. The following year, the percentage of host eggs that were parasitized by *O. pityocampae* increased more than double, from 7.3% to 17.7% and *O. pityocampae* became the most effective egg parasitoid. However, during the following two years, parasitism by *O. pityocampae* decreased considerably to only 5.53% in 1994 and to 6.31% in 1995. In spite of that, this Encyrtid remained the most effective among the egg parasitoids limiting *T. pityocampa* populations in this area.

20-103

FACTORS EFFECTING THE EFFICIENCY OF TRICHOGRAMMA COLONIZATION.

J. KOT

Institute of Ecology PAS, Dziekanow Lesny, Poland.

Biological control has been carried out in Poland since 1958, using species of *Trichogramma* Westw. The factors which have been shown by empirical investigation to be capable of exerting a decisive influence on the effectiveness of *Trichogramma* are:

1. Species and ecotypes.
 2. Quality of *Trichogramma* adults.
 3. Type of host.
 4. Numbers and time of parasitoid releases.
 5. Biocenotic relations.
 6. Climate and microclimate.
- Size of parasitoids, longevity and number of eggs laid, ratio females to males, resistance to variability in temperature and humidity, resistance to insecticides used and the searching ability.
- Attractiveness of the target host eggs and their duration.
- Numbers of parasitoids in relation to the plant surface, the coincidence of host appearance and the time of parasitoid releases.
- Density of host eggs and predation of parasitised eggs.
- All the factors mentioned above never occur simultaneously, but there are frequent instances when some overlap, making it difficult to analyse them.

20-105

SOME RECORDS ON THE *TRICHOGRAMMA* SPECIES ASSOCIATED WITH *DIATRAEA* IN THE NEW WORLD (HYMENOPTERA: TRICHOGRAMMATIDAE - LEPIDOPTERA: PYRALIDAE).R.A. Zucchi, J.D. Pinto¹, R.C. Monteiro

Departamento de Entomologia, Escola Superior de Agricultura Luiz de Queiroz, Universidade de São Paulo, Piracicaba, Brasil - ¹ Department of Entomology, University of California, Riverside, USA.

Among the *Diatraea* species found on sugar cane, *D. saccharalis* is the most common in several countries of the American continent. Therefore, in many of these countries, biological control programs are being carried out to control the sugar cane borer by releasing *Trichogramma*. However, in some cases, the specific names of *Trichogramma* have been used improperly and, there are no voucher specimens to verify the species identifications used in these programs. Consequently, a survey of records exclusively from the literature does not provide reliable information on the hosts and distribution of *Trichogramma*. The results of our studies are based on *Trichogramma* samples received for identification occasionally. Eleven species of *Trichogramma* from eggs of four *Diatraea* species from seven countries were identified as follows: USA- *T. exiguum*, *T. minutum* and *T. thalense* from *D. grandiosella* on corn. Mexico- *T. atopovirilia* on *D. grandiosella* and *D. considerata*, *T. exiguum* from *Diatraea* sp. and *T. fasciatum* from *D. saccharalis* (?). Dominican Republic- *T. fuentesi* from *D. saccharalis* on sugar cane. Brazil- *T. dissimilis*, *T. distinctum*, *T. galloi*, *T. jalmirezi* and *T. pretiosum* from *D. saccharalis* on sugar cane. Bolivia- *T. galloi* from *D. saccharalis* and *D. rufescens* on sugar cane, Paraguay- *T. galloi* from *D. saccharalis* on sugar cane, Uruguay- *T. galloi* from *D. saccharalis* on sugar cane; *T. pretiosum* from *D. saccharalis* on rice and sugar cane.

20-106

INDUCTION OF ADULT DIAPAUSE AND OVERWINTERING IN A PARASITOID WASP, *OOENCYRTUS NEZARAE*

T. Teraoka, H. Numata

Department of Biology, Faculty of Science, Osaka City University, Osaka, Japan

Ooencyrtus nezarae Ishii (Hymenoptera: Encyrtidae) is an egg parasitoid of true bugs. First, we reared *O. nezarae* on eggs of the bean bug, *Riptortus clavatus* Thunberg (Heteroptera: Alydidae) under various photoperiods and temperatures in the laboratory. Under short-day (10L-14D) conditions at 15 °C, all female adults entered diapause without vitellogenesis. Under long-day conditions at 20 °C, some adult females entered diapause. Then we kept eggs of *R. clavatus* parasitized by *O. nezarae* under conditions of natural photoperiod and temperature in Osaka, Japan. Diapause female adults emerged first in late October, and most female adults emerging in November entered diapause. The greater proportion of them overwintered, although no males did. Thus, only female adults of *O. nezarae* enter diapause under short-day conditions and low temperature and overwinter.

SELECTION OF A BIOLOGICAL CONTROL AGENT: HOST-ACCEPTANCE AND HOST PREFERENCE OF TWO SPECIES OF TRICHOGRAMMATIDAE

F. Fournier and G. Boivin¹Services Bio-Contrôle Inc., Sainte-Foy, Québec, Canada, ¹Agriculture et Agroalimentaire Canada, Saint-Jean-sur-Richelieu, Québec, Canada

Species of egg parasitoids of the Trichogrammatidae family are currently selected for the biological control of Lepidopterous pests (*Artogeia rapae*, *Trichoplusia ni* and *Plutella xylostella*) of cruciferous crops. Host acceptance and host preference of the three pests were measured for *Trichogramma buesi* and *Trichogrammatoidea bactrae*.

In no-choice experiments, host acceptance (proportion of females parasitizing at least one egg) by *T. buesi* was rapid for *T. ni*, 90% after 2 hours, and gradual for the two other hosts, ca. 50% after 2 hours and above 95% after 24 hours. *A. rapae* eggs were rejected by *T. bactrae* but acceptance of *P. xylostella* and *T. ni* was rapid, over 75% after 2 hours.

During a 4-hours choice experiment, *T. buesi* displayed a significant preference for *T. ni* and rejection of the two other hosts. *T. bactrae* preferred *T. ni*, rejected *A. rapae* and parasitized *P. xylostella* proportionally to its abundance. Video image analysis of a 20-minutes choice experiment gave the same results for *T. bactrae*. However, *T. buesi* displayed no significant host preference, *T. ni* and *P. xylostella* had similar acceptance/contact ratios and were parasitized proportionally to their relative abundance. *T. buesi* could show learning and be a more generalist parasitoid than *T. bactrae*.

20-107

FECUNDITY AND LONGEVITY OF *OOENCYRTUS PITYOCAMPAE* (MERCET) REARED ON EGGS OF A LABORATORY HOST, *NEZARA VIRIDULA* (L.)R. Tiberi⁽¹⁾, A. Niccoli⁽²⁾, P. Sacchetti⁽¹⁾⁽¹⁾ Istituto di Patologia e Zoologia forestale e agraria, Università di Firenze, Italy - ⁽²⁾ Istituto Sperimentale per la Zoologia Agraria, Firenze, Italy

Among the egg parasitoids of the Pine Processionary Caterpillar, *Thaumetopoea pityocampa* (Denis et Schiffmüller) (Lepidoptera, Thaumetopoeidae), only the Encyrtid *Ooencyrtus pityocampae* (Mercet) (Hymenoptera, Encyrtidae) was reared successfully in the laboratory on alternative hosts, especially Lepidoptera and Heteroptera. Among these, the Pentatomid *Nezara viridula* (L.) proved to be particularly suitable for the mass rearing of the parasitoid which are to be used in biological control programmes.

A wild strain of *O. pityocampae* from PPC egg masses was used to establish the laboratory rearing. Fecundity of *O. pityocampae* on the laboratory host increased from 50 eggs per female in the 1st generation developed on *Nezara* to 119 eggs after 28 generations. The average number of individuals that originated from each female increased from approximately 40 (in the 1st generation) to 93 after 28 reproductive cycles on the same host. The percentage of *O. pityocampae* females that accepted *N. viridula* eggs increased from 78.94% in the 1st generation to over 85% and reached 100% in the last generation tested. The females of the various generations began to oviposit in different moments of their live, which varied from a few to several days after emergence. Furthermore, the duration of the oviposition period varied greatly. The presence of two or three parasitoid females on the same egg mass did not seem to alter their reproductive capacity in any significant way. The longevity of the individuals varied from a minimum of 5 days (checked during the 6th generation) to a maximum of 63 days (during the 29th generation). On average, the most long-lived showed to be the females of the 12th generation (45 days).

20-109

RELEASE OF *TRICHOGRAMMA BRASSICAE* BEZDENKO ON GRAIN CORN FOR THE BIOLOGICAL CONTROL OF EUROPEAN CORN BORER, *OSTRINIA NUBILALIS* (HÜBNER), IN NORTH-EASTERN ITALY

P. Zandigiacomo, M. Greatti

Dipartimento di Biologia applicata alla Difesa delle Piante, Università di Udine, Italy

During the years 1991-95 research on the biological control of the European corn borer (ECB), *Ostrinia nubilalis* (Hübner), with the egg parasitoid *Trichogramma brassicae* (Bezdenko) was carried out in north-eastern Italy. About 200 000 parasitoids per hectare were released on grain corn three times against the ECB second generation using cardboard capsules containing parasitized eggs of *Ephestia kuehniella* Zeller; the first release occurred at the beginning of the ECB oviposition period (end of July), while the second and third ones followed at 7-10 day intervals. Parasitoids produced at Biolab (Cesena, Italy) or at Biotop (Valbonne, France) were used.

In treated fields the ECB egg masses parasitization ranged from 25% to 90% and was always higher than in untreated ones; the activity of naturally occurring trichogrammatids was delayed and rarely exceeded 20%. In fields where the parasitoids were released at 200 points per hectare the parasitization rate (45%) was higher than in those where *T. brassicae* was distributed at 100 points/ha (26%). The parasitization rate reduced rapidly from the release points and was very low (<15%) at a distance of over 10 m; moreover the parasitoids shifted downwind. A local strain of *T. brassicae* was constantly and significantly more efficient (average parasitization 74%) than a French strain (50%). When the oviposition period of ECB continued during to the first decade of September a 50-90% egg masses parasitization was observed up to 4 weeks after the third release.

Even though the parasitization rates observed were high, a considerable reduction in the number of ECB larvae and an increase in crop yield were not always observed at the harvest. Further research should be carried out before applying this biological method extensively in northern Italy.

If invited speaker, indicate title of session and name(s) of organizer(s):

20-110

ANAGRUS FENNICUS SOYKA (HYMENOPTERA: MYMARIDAE), EGG PARASITOID OF *CICADELLA VIRIDIS* (L.) (HOMOPTERA: CICADELLIDAE) IN ITALY

E. Chiappini

Istituto di Entomologia e Patologia vegetale, Facoltà di Agraria, Università Cattolica del Sacro Cuore, Piacenza, Italy.

Anagrus fennicus (Hymenoptera: Mymaridae), introduced by Soyka in his key of *Anagrus* females (1955) as a new species, together with 33 others, was never described in detail.

In the review of the European species of the genus (Chiappini, 1989), I kept this species as valid and added some distinguishing characters that I deduced from study of the holotype.

A. fennicus holotype was collected in Finland (28° lat., 68°10' long.), on 29-VIII-1938 and, up to now was the only specimen of the species available. No information existed on biology and hosts.

Thus, it is here recorded for the first time in Italy on a known host.

The specimens utilized for this study were reared from *Cicadella viridis* (L.) overwintering eggs deposited at the base of *Carex riparia* Curtis (Cyperaceae) leaves, collected periodically during the winter months, from September to February, in uncultivated areas along the Po river in Piacenza province in Italy.

A morphological description of *A. fennicus* is given, together with biological, ecological and ethological observations and, on these bases, its specific identity is discussed.

20-112

HOST NUMBER AND SPATIAL DISTRIBUTION INFLUENCE ON *TRICHOGRAMMA* (HYMENOPTERA) HOST ACCEPTANCE AND FECUNDITY

N.D. Voinovich, S. Ya. Reznik, T. Ya. Umarova
Zoological Institute, St. Petersburg, Russia

Experiments with different *Trichogramma* species show that the percentage of females which accept *Sitotroga cerealella* Oliv. (Lepidoptera, Gelechiidae) for parasitization depends significantly on the number and spatial distribution of host eggs. The rest of *Trichogramma* females that refused *Sitotroga* eggs have many mature ovarian eggs, sometimes contact the host, but their parasitization behavior is interrupted at the stage of arrestment and host recognition.

In different *Trichogramma* species, over the range of the number of host eggs from 5 to 90, the percentage of parasitizing females increases by two to ten times. Females placed in Petri dishes 9 cm in diameter accept *Sitotroga* eggs more often than females placed in Petri dishes 4 cm in diameter, all other factors being the same. One artificial patch consisting of 60 host eggs provokes parasitization in significantly lower percentage of wasps than 12 patches consisting of 5 eggs each. In some cases the spacing between patches also influences the acceptability of host eggs. The mechanisms underlying the observed effects are not clear yet.

An increase in the number of host eggs may possibly result in higher concentration of kairomone which arrests the parasitoid and starts parasitization. Spatial distribution of eggs may influence host acceptance through the kairomone concentration as well. However, both visual and tactile perception may also participate in *Trichogramma* females reaction to the number and spatial distribution of host eggs.

20-111

INFLUENCE OF PARASITISM SURFACE POSITION ON *TRICHOGRAMMA CORDUBENSIS* (HYMENOPTERA: TRICHOGRAMMATIDAE) HOST FINDING ABILITY

P. Garcia, H. Câmara & J. Tavares

Departamento de Biologia, Universidade dos Açores, Ponta Delgada, Portugal

The oophagous parasitoids of the genus *Trichogramma* are used worldwide as biological control agents against several agricultural pests. The success of parasitism in the fields depends, amongst other factors, of the parasitoid host finding ability, which is related with the parasitism surface position. Therefore this study was concerned with *T. cordubensis* parasitism distributions over several surface parasitism levels, and inner or upper parasitism surfaces. For this species, the parasitism significantly increased with the increasing height of the parasitism surface position: an average of 9.6 parasitized eggs for the inner and upper surfaces of the egg card placed at 14 cm, 33 at 28 cm, 55.8 at 42 cm, 72.6 at 56 cm and 139 at 70 cm. For each parasitism surface level, the average of parasitized eggs per egg card was always higher at the inner parasitism surfaces, although significant differences were only observed for the egg cards placed at 42 and 56 cm of height.

20-113

DNA POLYMORPHISM ANALYSIS OF *TRICHOGRAMMA* (HYMENOPTERA: TRICHOGRAMMATIDAE) IN JAPAN

Y. Sasama, M. Muraji¹, K. Hirai², S. Wakisaka, N. Yasudomi, Y. Takagi

Otsuka Chemical Co., LTD., Naruto, Tokushima, Japan - 1 National Institute of Sericultural and Entomological Science M. A. F. F., Tsukuba, Ibaraki, Japan - 2 National Agriculture Research Center, Tsukuba, Ibaraki, Japan.

For the quality control of *Trichogramma* as a biological agent, an efficient system to maintain strains is first thing to be established. In the present study, we evaluated reliability of polymorphisms in an internal transcribed spacer (ITS2) of ribosomal DNA and cytochrome oxidase III gene (COIII) of mitochondrial DNA as probes for different species and strains of *Trichogramma*. Nucleotide sequences were determined for ITS2 and COIII of several species and strains of *Trichogramma* collected in Japan. Both ITS2 and COIII showed sequences specific to each species examined, except *T. chilonis*. Thus, a possibility was shown to use gene polymorphisms as probes to identify strains of *Trichogramma*.

20-114

SUPERPARASITISM BY A NAIVE EGG PARASITOID, *TRICHOGRAMMA CHILONIS* ISHII (HYMENOPTERA : TRICHOGRAMMATIDAE) : EFFECT OF ELAPSED TIME AFTER FIRST OVIPOSITION BY CONSPECIFICS ON HOST DISCRIMINATION

I.Ohta, K.Miura, M.Kobayashi

Laboratory of Insect Pest Control, Chugoku National Agricultural Experiment Station, Fukuyama, Hiroshima, Japan

This study was carried out to investigate whether females of *Trichogramma chilonis* Ishii which had never oviposited in any host egg after emergence could discriminate between unparasitized and parasitized hosts by conspecific females or not. Mediterranean flour moth, *Ephestia kuehniella* (Zeller) eggs containing an immature parasitoid of either 0, 1, 2, 3, 5, 7 or 9 ages in days or eggs containing nothing (i.e. unparasitized eggs) were offered to *T.chilonis* females. Although the female parasitoids oviposited in unparasitized and 0 day parasitized eggs, they did only in a part of eggs of 1 and 2 days and avoided all the eggs more than 3 days. Moreover, two parasitoids were allowed to oviposit in the same host egg with an interval within 10 minutes or of 24 hours. Emerging rate of second offsprings from superparasitized hosts with time interval of less than 10 minutes was as much as first ones. However, that of 24 hours interval decreased down 20%. These results suggested that inexperienced females of *T.chilonis* could distinguish unparasitized and parasitized host eggs, and might adaptively oviposit in parasitized hosts according to survival of their offsprings.

20-116

A STUDY ON USING *TRICHOGRAMMA DENDROLIMI* TO CONTROL *MICROMELALOPHA TROGLODYTA* GRAESER

Gui-jun Wang, Li-wei Hou, et al.

Forest Quarantine Station of Jilin Province, Changchun, China.

Micromelalopha troglodyta is extensively dispersed over northeast China, north China, northwest China and east China. Its host plants include poplar, elm, birch and willow. They mainly endanger poplar in the wind-break forest of west Jilin Province. All leaves of the host plants were eaten up while they broke out, seriously affecting the growth and development of the trees and causing their withering in winter. *Trichogramma dendrolimi* was used to control *M. troglodyta* in a Station in Jilin Province in 1988. The experiment was carried out as follows: (1) Unfertilized eggs of *Antheraea pernyi* were used to propagate *T. dendrolimi* for 8 generations. (2) The reared parasitoids were released from 3rd-17th in June when the moths were laying eggs. (3) During the experiment, 20000 *T. dendrolimi* were released per mu, and the release was repeated for 4 times so that a total of 80000 *T. dendrolimi* per mu were released. (4) The parasitoids were released at a height of 2 meters above the ground, and the control spot was located windward away 1000 meters. The parasitic rate of the eggs ranged from 65-100%, 82% on average. The population of *M. troglodyta* declined 44% lower than that of the control spot.

EGG PARASITOID OF *PHORACANTHA SEMIPUNCTATA* F. (COLEOPTERA: CERAMBYCIDAE) IN SOUTHERN PORTUGAL. 1- FIELD STUDIES OF THE EFFICIENCY OF *AVETIANELLA LONGOI* SISCARO (HYMENOPTERA: ENCYRTIDAE)

M. Lima¹, J. Araújo¹.

Departamento de Biologia, Universidade de Évora, apartado 94 7001 Évora Codex, Portugal

The eucalyptus longhorned borer *Phoracantha semipunctata* (Coleoptera: Cerambycidae), is a major pest causing serious damage in portuguese eucalyptus stands. Since 1992, the presence in Portugal of *Avetianella longoi* Siscaro (Hymenoptera: Encyrtidae), an egg parasitoid of *P. semipunctata*, has contributed to the reduction of the population of this insect. It may be useful, to employ this parasitoid in an Integrated Pest Management Program.

However, there has been little information on their effectiveness as a parasite.

The purpose of this investigation is to evaluate the effectiveness of *A. longoi* as a biological control agent in the field. During the summer of 1994 and 1995, every weeks, were collected egg layings of *P. semipunctata* in attacked trees.

Preliminary results of parasitized eggs, emerged parasitoids and sex-ratio were determined

20-117

TRACER DETERMINE SPREAD DISTANCE OF *TRICHOGRAMMA* WASPS REARED IN ARTIFICIAL HOST EGGS USING ³²P MARK IN THE CORN FIELD

Wu Juwen, Zhang Zhili, Wang Suqin, Gong Yunxiu

Institute of Plant and Environmental Protection, Beijing Academy of Agriculture and Forestry Sciences, P. O. Box 2449, Beijing 100081, China

Trichogramma wasps reared in artificial host eggs were marked by ³²P in honey water in 16 hours, 10000 wasps of each species of *Trichogramma* were released in the corn field in each treatment. To investigate spread trace, fresh corn borer eggs oviposited in laboratory were placed at 10 m intervals from release wasp point (as the center of a circle) to all around. The results showed that 60% wasps of *T. chilonis* (in artificial eggs) could fly to 30 m from the center of circle, 20% to 50 m, 10% to 60 m and 10% to 70 m; 62.5% wasps of *T. dendrolimi* (in artificial eggs) could fly to 40 m, 12.5% to 60 m, 12.5% to 80 m, 12.5% to 90 m. These results showed no different from *T. dendrolimi* wasps (in *Antheraea pernyi* eggs). It indicated that artificial host egg could rear normal *Trichogramma* wasps.

20-118

A FIELD TRIAL OF USING *TRICHOGRAMMA CHILONIS* REARED IN ARTIFICIAL EGGS TO CONTROL *HELICOVERPA ARMIGERA*

Zhang Zhili, Wu Juwen, Wang Suqin, Gong Yunxiu

Institute of Plant and Environmental Protection, Beijing Academy of Agriculture and Forestry Sciences, P.O. Box 2449, Beijing, 100081, China

A field trial was carried out using *T. chilonis* reared in artificial eggs to control *Helicoverpa armigera* in the cotton field, Hebei province in 1994. There releases were made at the second generation egg stage, 351000 wasps per hectare. The result showed that the parasitising rate was 46.4%, the natural parasitising rate 0. There were five releases at the third generation egg stage, 1530000 wasps per hectare, parasitising rate 58.4%, the natural parasitising rate also 0.

T. chilonis reared in *Antheraea pernyi* egg was as a control. There were four releases at the egg stage of the third generation, 1125000 wasps per hectare. The parasitising rate was 74.6%, higher than that in the artificial egg wasp areas. When *T. cilonis* reared in *A. pernyi* was released at egg stage of the second generation, the parasitising rate was 67.8% at normal years. The main reason of lower parasitising rate this year was abnormal climate in which temperature was much higher and humidity was much lower than usual. There were 27 days in which temperature was above 30°C; 16 days above 33°C; 11 days above 35°C; the lowest humidity was 3.2%. The upper limit of development temperature of *T. chilonis* was 33°C at laboratory. *T. chilonis* released in the field could only survive 16hrs.

This trial was arranged at the area in which *H. armigera* has higher resistance to agricultural chemicals. The control efficiency in the wasp-releasing areas (*Trichogramma* of artificial egg and natural egg) were higher than that in chemical control area (eight spraying, 24 bollworms on one hundred plants). The mortalities of *H. armigera* were 58.3% and 83.3% in the wasp-releasing areas, the percentages of borehole cotton buds and bolls were decreased to 80.8% and 84.6% respectively, the number of natural enemies (ladybirds and lacewings) was doubled.

20-120

NON - KILLING EFFECTS OF CERTAIN INSECTICIDES ON THE DEVELOPMENT AND PARASITIC FEATURES OF *TRICHOGRAMMA*B. Ramesh¹ and P. Baskaran²

Department of Entomology, Faculty of Agriculture, Annamalai University, Tamil Nadu - 608 002, India.

The effect of seven insecticides recommended for the control of several lepidopteran pests was studied under laboratory conditions on adult parasitic features and development of *Trichogramma*. The concentration of the insecticides are those recommended for field application viz., Endosulfan 0.0175%, Monocrotophos 0.09%, Phosphamidon 0.09%, Cypermethrin 0.016%, Achook 0.5%, Dipel 0.004%, and Nimbecidine 0.002%. Biopesticides Achook, Nimbecidine and Dipel were found to be completely safer both to adult parasitic features and developmental stages of *Trichogramma*. Among insecticides, Endosulfan was comparatively safer to the parasitoids, while Monocrotophos and Phosphamidon although had inhibitory effects were better than Cypermethrin which was found to be highly lethal to the parasitoids.

20-119

DOES THE HOST AVAILABILITY REGULATE THE LONGEVITY AND FECUNDITY OF *TRICHOGRAMMA* ?B. Ramesh¹ and P. Baskaran²

Department of Entomology, Faculty of Agriculture, Annamalai University, Tamil Nadu - 608 002, India.

Biological hypothesis that the female parasitoids could adjust their fecundity schedule according to host availability and tradeoff longevity with fecundity was tested in a thelytokous egg parasitoid *Trichogramma brasiliensis* Ashmead. The tradeoffs between early and late reproduction revealed that the test insect was able to exploit its hosts as much as possible during the first day or first few days of adult life. During periods of no host, it was able to adjust its fecundity schedule and compensate early reduction in the later stages. Secondly, in tradeoffs between longevity and fecundity there existed a negative relationship between survival and reproduction i.e. oviposited females lived shorter. From these two observations it appears that *T. brasiliensis* responded positively to the hypothesis and hence their suitability under fluctuating host availability in inundative releases can be recommended to achieve effective control.

20-121

IMPACT OF PLANT CHARACTERS ON *TRICHOGRAMMA* SEARCHING BEHAVIOR: A CASE STUDY WITH PIGEONPEA *CAJANUS CAJAN*J. Romeis, T. G. Shanower, C. P. W. Zebitz¹

Crop Protection Division, International Crops Research Institute for the Semi-Arid Tropics (ICRISAT), Patancheru, India - 1 Institut für Phytomedizin, Universität Hohenheim, Germany

Trichogramma spp. only rarely parasitizes eggs of *Helicoverpa armigera* (Hübner) on pigeonpea, while on other plants high parasitism levels of this host are found. The reasons for the obvious rejection of pigeonpea were studied in the laboratory and in the field in a pigeonpea:sorghum intercrop.

Olfactometer studies have shown that odors emitted by pigeonpea plants in the reproductive stage, the growth stage preferred by *H. armigera* for oviposition, repel the searching parasitoids so that landing on the plants may be avoided. In comparison, the odor of flowering sorghum panicles, a plant from which high parasitism levels are reported, were attractive to the parasitoids.

After landing on the pigeonpea plant three other factors mediate the searching behavior of the parasitoids: (1) As shown in a filterpaper bioassay, hexane surface washings from pods and leaves contain contact repellent(s); Walking speed on leaves increased significantly after washing with hexane, (2) glandular and nonglandular trichomes on the reproductive plant structures inhibit walking behavior, and (3) the parasitoids are trapped by the sticky exudates secreted by glandular trichomes. The latter factor seems not to be an important parasitoid mortality factor in the field.

In a pigeonpea:sorghum intercrop in the field, the high *Trichogramma* population in sorghum did not move over into the pigeonpea crop where a very low parasitoid density was observed throughout the season.

20-122

PRIMING *APHYTIS*: BEHAVIORAL MODIFICATION OF HOST SELECTION BY EXPOSURE TO A SYNTHETIC CONTACT KAIROMONE

J. D. Hare, D. J. W. Morgan

Department of Entomology, University of California, Riverside, CA USA

The introduced parasitic wasp, *Aphytis melinus* DeBach (Hymenoptera: Aphelinidae), utilizes a kairomone, *O*-caffeoyltyrosine (*OCT*), to recognize California red scale, *Aonidiella aurantii* (Maskell) (Homoptera: Diaspididae). Wasps used in augmentative release programs for California red scale on California citrus are reared on oleander scale, *Aspidiotus nerii* Bouché (Homoptera: Diaspididae), themselves reared on squash. The goals of this study were: 1) to determine if long-term rearing on oleander scale caused *A. melinus* to develop a preference for oleander scale, 2) to determine if the preference of oleander-reared *A. melinus* for California red scale might be enhanced by exposing them to synthetic *OCT* in the laboratory, and, if so, 3) to determine if oleander-reared but *OCT*-primed wasps parasitized a greater proportion of California red scale in the field than unconditioned wasps.

Wasps that emerged as adults isolated from their hosts retained a strong preference for California red scale regardless of rearing host. This preference was reduced if wasps were allowed to emerge from oleander scale, thus acquiring early adult experience with oleander scale. The preference for California red scale was restored, however, by exposing wasps reared on oleander scale to synthetic *OCT*.

Preliminary field results suggest that wasps primed to *OCT* parasitize more California red scale than control wasps. Exposure of *A. melinus* reared in commercial insectaries to *OCT* prior to release may be a means to improve the effectiveness of augmentative release programs to control California red scale.

20-124

Response of *Chrysopa septempunctata* to pheromones of aphidsK.S. Boo, I.B. Chung¹, L.J. Wadhams, J.A. Pickett²
Dept. of Agric. Biol., Seoul Natl. Univ., Suwon, Korea - 1 Biol. Ecol. Chem. Dept., Rothamsted Exptl. Station, Harpenden, Herts., AL5 2JQ. United Kingdom - 2

Sex pheromone, (4a*S*,7*S*,7a*R*)-nepetalactone and (1*R*,4a*S*,7*S*,7a*R*)-nepetalactol, and alarm pheromone, (E)- β -farnesene, of aphids were tested for their effects on *Chrysopa septempunctata*, one of the principal predator of aphids. In EAG tests, both of sex pheromone components showed a responsiveness but alarm pheromone gave no difference from that of solvents. Sex pheromone components also showed an attractiveness in a Y-tube olfactometer and field trapings with a higher attractiveness of (4a*S*,7*S*,7a*R*)-nepetalactone but alarm pheromone showed no evidence for attraction in both of laboratory bioassay and field trapping. Interestingly, spring and summer populations of *C. septempunctata* gave no response to sex pheromone components either.

20-123

PREDATORY MITES CEASE TO RESPOND TO PLANT VOLATILES: A CONTAGIOUS PHENOMENON

Conny Schütte, Marcel Dicke, Tesfaye Negash & Herman Dijkman

Department of Entomology, Wageningen Agricultural University, Wageningen, The Netherlands.

During foraging for spider-mite prey, the predatory mite *Phytoseiulus persimilis* is highly attracted to plant volatiles that are produced in response to spider-mite feeding. This phenomenon has been recorded consistently for several predator populations during more than 10 years. During a recent 5-year monitoring period, we have recorded for two of these populations that the predators lost their attraction to prey-infested plants.

The inability to respond to plant volatiles is accompanied by several other phenomena such as: high crystal load in the Malpighian tubules, reduced reproduction, reduced size, increased mortality.

The cause of this syndrome appears to be a non-genetical change in the predators that is contagious. When a predator from a 'normal' population is brought together with an individual from a non-responding population, the phenomena of the latter predator can be found in the 'normal' predator within a few days.

20-125

MEDIATION OF HOST LOCATION BY VOLATILES IN THE GRAIN WEEVIL PARASITOID *LARIOPHAGUS DISTINGUENDUS* (FÖRST.) (HYMENOPTERA: PTEROMALIDAE)

J.L.M. Steidle

Freie Universität Berlin, Institut für Zoologie, Angewandte Zoologie / Ökologie der Tiere, Berlin, Germany

The role of volatiles for host location in parasitoids was examined in a tritrophic system, consisting of *Lariophagus distinguendus* (Först.), a parasitoid of different stored product beetles, the grain weevil *Sitophilus granarius* (L.), a worldwide pest which develops in kernels of stored grain, and kernels of wheat (*Triticum* sp.).

The experiments were performed in a four chamber olfactometer, at first using female parasitoids with oviposition experience. The parasitoids were attracted by volatiles emanating from uninfested and infested wheat kernels. They were able to differentiate between infested and uninfested kernels with infested kernels being more attractive. The potential volatile sources of an infested wheat kernel are weevil larvae, their frass and the damaged kernel. From these, the frass turned out to be most attractive to the parasitoids followed by infested kernels from which the larvae and the frass had been removed. These kernels were as attractive as uninfested, but cutted kernels. This indicates that their attractivity could be due to the mechanical damage of the kernels by the feeding weevil larvae. The larvae had no significant attractive effect. Experiments with inexperienced female parasitoids which were kept isolated from uninfested and infested grain upon emergence, indicate an increase of the responses to frass, mechanically damaged kernels and uninfested kernels due to experience.

Thus *L. distinguendus* uses volatile cues from both trophic levels, host (frass) and host plant (grain and damaged grain) for host location and modulates the response to these cues by experience.

20-126

RESPONSES OF PARASITOIDS OF APHIDS TO OLFACTORY CUES OF THE HOST PLANT OF THEIR PREY

H. F. van Emden

School of Plant Sciences, The University of Reading, United Kingdom

A range of parasitoids of aphids from monocotyledonous and dicotyledonous plants, both trees and herbs, all reacted positively to the odour of the plant species on which they had developed, even when they emerged from mummies detached from plants. The odour of the plant was preferred to that of the prey aphid and its honeydew.

Such discrimination in favour of the plant on which the parasitoid had developed was even shown by *Aphidius rhopalosiphii* De Stef. between different cultivars of wheat. It is suggested that it is the balance of the common volatiles from wheat, rather than cultivar-specific characters, which underlies the discrimination.

If the parasitized aphids are transferred to a different wheat cultivar at various times after parasitisation, it can be shown that it is the cultivar experienced before pupation by the parasitoid which is preferred on emergence of the adult. This appears to vindicate Hopkins' 'host selection principle' proposed as long ago as 1917, that chemical experiences of the larva can be transferred to the adult through the pupal stage in an endopterygote insect. Previous evidence for Hopkins' principle has never been accepted as free of alternative interpretation and unfortunately this example of aphid parasitoids also turns out clearly not to be an example of the principle. However, preferences of parasitoids seem to be revealed which are normally masked by previous experience of host plants.

20-128

THE ROLE OF CHEMICALS FROM DAMAGED LEAF IN HOST FINDING BY PARASITIC WASPS

Y. Sato, N. Ohsaki*, S. Yano**, J. Takabayashi**

Kyoto College of Medical Technology, Sonobe, Kyoto, Japan

*Entomological Laboratory, Faculty of Agriculture, Kyoto University, Kyoto, Japan

**Laboratory of Ecological Information, Graduate School of Agriculture, Kyoto University, Kyoto, Japan

Parasitoids use several chemicals of host food plant origin as cues of presence of host. The functions of such chemicals differ according to their volatility: parasitoids can detect volatile cues at a distance from a food plant whereas they can detect nonvolatile cues by contact chemoreceptor to confirm a host food-plant. In addition the damage by host feeding may induce a plant to produce some specific compounds. Such host-induced plant chemicals seem to be reliable cues for the parasitoids on the presence of hosts on the plant.

It is a matter of argument on the evolution of such chemical cues whether the plant has evolved to produce the chemicals or whether the parasitoid has evolved to detect the chemicals closely related with host presence. We will attempt to examine the hypothesis that the plant has evolved to produce some chemicals leading the parasitoid to host larvae in the following two systems.

(1) Crucifer plants, *Pieris rapae* larvae, *Cotesia glomerata*(2) Corn plants, *Pseudaletia separata* larvae, *Cotesia kariyai*

20-127

LEARNING OF PLANT CHEMICALS BY THE EGG-LARVAL PARASITOID, *ASCOGASTER RETICULATUS* (W.) (HYMENOPTERA: BRACONIDAE)

Y. Kainoh and T. Honda

Institute of Agriculture and Forestry, University of Tsukuba, Tsukuba, Ibaraki 305, Japan

Ascogaster reticulatus Watanabe is the egg-larval parasitoid of the smaller tea tortrix, *Adoxophyes* sp. (Lepidoptera: Tortricidae). The females find host eggs using host kairomones located in wing scales and the egg mass surface. We found that the females could learn plant chemicals associated with the host egg mass. We treated a line of the plant extract (EtOH) on the bottom of a petri dish (9cm in dia), and the host egg mass was put at the center. One female was released in the dish and her behavior was observed until she began to oviposit. One or two minutes after the onset of oviposition, the wasp was gently removed from the host egg mass and put back in a cage. This procedure (training) was repeated one to three times with one hour's interval. Next, the wasp was released in the dish only with the plant extract, and the wasp responded to the treated part with her antennae and walked along the line. We measured the distance of walking on the line within 3 min, which was the criteria to see the learning response of female wasps. Their response increased with a corresponding increase in training time. We tested leaves of two plant species, and the response was stronger in the tea leaves, the host plant of *Adoxophyes* sp. than mulberry, non-host plant. Once they learned of the plant chemical after 3 experiences, they responded to it after 24 hrs to a lesser degree, and did not respond at all after 48 hrs.

20-129

VIBRATIONAL INTERACTIONS BETWEEN A LEAFMINER AND ITS PARASITOID

R. Meyhöfer, J. Casas*, S. Dorn

Institute of Plant Sciences, Swiss Federal Institute of Technology (ETH), Zurich, Switzerland - * University of Tours, Tours, France

Parasitoids rely on visual, chemical, and mechanical stimuli for efficient host location. If the host is concealed, like with many leafminers, substrate vibrations triggered by the host or the parasitoid may play an important role for interactions between both opponents.

We focused on behavioural interactions between the parasitoid *Sympiesis sericeicornis*, Nees (Hym. Eulophidae) and the apple leafminer *Phyllonorycter malella*, Gcr. (Lep. Gracillariidae). At different locations on the leaf lamina vibrations were measured using a laser vibrometer and were characterised by temporal pattern, amplitudes, and frequencies¹. Vibrations triggered by a moving larva are distinguishable over the whole leaf from background noise, and are specific to host stage and behaviour. The behavioural interactions between host and parasitoid were investigated using combined ethograms. The moving behaviour of the larva inside the mine strongly affects some of the transition probabilities of the parasitoid's activity. However the host's movements did not lead to obvious vibrotaxis. On the other hand insertion of the parasitoid's ovipositor has a significant influence on larval behaviour². Thus, both opponents interact by means of vibrational information incidentally transmitted via substrate.

Cues for oviposition choice in *Episyrphus balteatus* (Diptera: Syrphidae)

L. S. NGAMO TINKEU & Th. HANCE, Université Catholique de Louvain. Unité d'Écologie et de Biogéographie. Louvain-la-Neuve, Belgium

Aphid predators have to cope with unstable food supply for their offsprings because aphid colony have currently a short life time and may decline before predator offsprings maturation (Hemptine et al, 1993). In this context, a gravid female of *E. balteatus* have to take the decision to lay eggs in an aphid colony and thus must estimate the risk for her progeny in terms of food availability and intraspecific competition.

Our aim was to determine the cues that guide her choice. We tested the presence of aphid and their density; the presence of honeydew; also the presence of eggs or larvae of other individuals and the possibility of marking the oviposition site.

It appears that two kinds of chemical cues help Syrphid in their choice: the aphid odour enhancing oviposition and Syrphid's eggs and larva inhibiting it.

RESPONSE OF *TRICHOGRAMMA EVANESCENS* TO SYNTHETIC (Z,E)-9,12-TETRA-DECADENYL ACETATE (TDA), A SEX PHEROMONE COMPONENT OF *EPHESTIA KUEHNIELLA* AND *PLODIA INTERPUNCTELLA* (HYMENOPTERA: TRICHOGRAMMATIDAE - LEPIDOPTERA: PYRALIDAE)

M. Schöller and S. Prozell

Federal Biological Research Centre for Agriculture and Forestry, Institute for Stored Product Protection, Berlin, Germany.

In field trials to evaluate *T. evanescens* WESTWOOD for biological control of stored product pest moths, the egg parasitoids were found on delta traps containing TDA. The possible use of the moth sex pheromone as a kairomone by *T. evanescens* was therefore studied.

In a four-armed airflow olfactometer, the position of mated wasps was observed directly and recorded using computer software. For a period of ten minutes one airflow permeated with TDA was tested against three others containing clean air. The experiments were conducted with naive females, females with oviposition experience and females which had oviposited in the presence of TDA.

Females which had previously oviposited in the presence of TDA spent significantly more time walking in the odour field containing TDA compared to clean air. Such a response was not elicited in both naive females and females with oviposition experience.

It is suggested that the females responding to TDA learned to use the moth sex pheromone as a kairomone. Learning may be especially important for host location in generalist parasitoids which frequently oviposit in eggs belonging to host species which have not been previously encountered.

As naive females were released in the field trials and the number of *T. evanescens* in delta traps was low, there seemed to be little impact of the monitoring programme on the fate and the effectiveness *T. evanescens*.

20-132

HOST SEARCHING BEHAVIOR OF *SYMPIESIS STRIATIPES* (ASHMEAD) (HYMENOPTERA: EULOPHIDAE), A PARASITIC WASP OF THE CITRUS LEAF MINER *PHYLLOCNISTIS CITRELLA* STAINTON (LEPIDOPTERA: GRACILLARIDAE)

M. Fukui and S. Takahashi

Research Division of Pesticide Biology, Pesticide Research Institute, Faculty of Agriculture, Kyoto University, Kyoto, Japan

Female parasitic wasps of *Sympiesis striatipes* (ASHMEAD) attack the larvae of the citrus leaf miner *Phyllocnistis citrella* STAINTON that infest young growing leaves of citrus trees. Host searching behavior by the females wasps on the unmined lamina and on the mine of a citrus tree *Citrus unshiu* M. c.v. SUGIYAMA was observed with a video camera under semi-natural conditions.

The observed paths of host searching behavior of the wasps were segmented based on a temporal sampling method (wasp's movement per unit time). Then the segmented paths, i.e.steps, were analyzed for the frequency distributions of turning angles and correlations between successive searching steps. The analyses results revealed that the wasps detect and locate the host using cues coming from the mine made by the host and the host itself rather than at random.

In addition, the observed paths of host searching behavior were segmented and analyzed using a spatial sampling method (wasp's movement per unit distance). Results of searching behavior analyzed with the spatial sampling method gave poorer information in comparison with those analyzed with the temporal sampling method.

The application advantage of the temporal sampling method to the analyses of host searching behavior by the wasp is discussed.

20-133

CAN PARASITOID FLIES REGULATE THEIR CLUTCH SIZE IN RESPONSE TO HOST DENSITY?

S. Nakamura

Japan International Research Centre for Agricultural Sciences, Tsukuba, Japan

Effect of host encounter rate and host density per patch on the oviposition decision of *Exorista japonica* (Diptera: Tachinidae) females was studied in the laboratory, and their ability of host discrimination was examined. The number of eggs laid per bout increased as the rate of host encounter decreased and as host density per patch increased. When an unparasitized and a parasitized host were simultaneously presented to a female for 60 min, females did not discriminate between an unparasitized and a parasitized host with 5 eggs, but did between an unparasitized and a parasitized host with 10 eggs. The rate of host encounter also affected the host discrimination. Females did not avoid oviposition even on a parasitized host with 10 eggs when they encountered hosts at the interval of 24 h, but they laid less eggs on the parasitized host at 1 min interval of the host encountering rate. The results thus indicated that *E. japonica* females had the ability not only to regulate clutch size with the host density (the rate of host encounter) but also to discriminate between parasitized and unparasitized hosts.

20-134

THE ROLE OF HOST-INDUCED PLANT SYNOOMONES ON IN-FLIGHT ORIENTATION OF THE APHID PARASITOID *APHIDIUS ERVI* HALIDAY (HYMENOPTERA, BRACONIDAE)
E. Guerrieri, Y.-J. Du¹, G. Poppy¹, W. Powell¹, F. Pennacchio², E. Tremblay

Dipartimento di Entomologia e Zoologia Agraria, Università di Napoli "Federico II", Portici (Na), Italy - ¹Entomology & Nematology Department, IACR-Rothamsted, Harpenden, Herts, U.K. - ²Dipartimento di Biologia, Difesa e Biotecnologie Agro-Forestali, Università della Basilicata, Potenza, Italy

The aphid parasitoid *Aphidius ervi* Haliday is attracted by volatiles released by broad bean (*Vicia faba*) plants infested by the pea aphid, *Acyrtosiphon pisum* (Harris). Previous studies demonstrated that the attractiveness of infested plants was not significantly reduced when they were tested soon after removing the aphids. To assess the origin of the involved volatiles the basal leaves of a broad bean plant were isolated and infested with mixed instars of *A. pisum*, and the apical part of the plant was subsequently used as an odour source in a wind tunnel bioassay. These experiments demonstrated that attractive plant volatiles are systemically induced by aphid feeding and suggested that the biosynthesis of these compounds is dependent by host-induced changes of plant metabolism. *A. ervi* females were also able to discriminate between pea aphid infested plants and those infested by the non-host *Aphis fabae*. The isolation and chemical analysis of volatiles from infested plants showed the occurrence of compounds which appeared to be attractive to *A. ervi* females. However, most of these compounds were also detectable in intact plants, even though aphid damaged plants showed a significant alteration of their synthetic rate and relative ratio.

20-136

THE PHORETIC EGG PARASITOID, *TELENOMUS EUPROCTIDIS* (HYMENOPTERA: SCELIONIDAE), USES SEX PHEROMONE OF THE TUSsock MOTH *EUPROCTIS TAIWANA* (LEPIDOPTERA: LYMANTRIIDAE) AS A KAIROMONE

N. Arakaki, S. Wakamura, T. Yasuda
Department of Insect Physiology and Behavior,
National Institute of Sericultural and
Entomological Science, Tsukuba, Ibaraki 305,
Japan

The phoretic egg parasitoid, *Telenomus euproctidis* (Hymenoptera: Scelionidae), was found more frequently on virgin than mated female, *Euproctis taiwana* (Lepidoptera: Lymantriidae), when virgin and mated moths were exposed concurrently in the field for 24 h. Synthetic component of the moth's sex pheromone *E. taiwana*, (Z)-16-methyl-9-heptadecenyl isobutyrate, attracted both the wasp, *T. euproctidis*, and male *E. taiwana*. These findings suggest that *T. euproctidis* uses the sex pheromone of the female moth, *E. taiwana*, as a kairomone to locate host female moth and through her the host eggs.

20-135

COLOUR VISION AND OVIPOSITION BEHAVIOUR IN *APHIDIUS ERVI* HALIDAY (HYMENOPTERA, BRACONIDAE)

D. Battaglia, F. Pennacchio, A. Romano, A. Tranfaglia, G. Poppy¹, W. Powell¹

Dipartimento di Biologia, Difesa e Biotecnologie Agro-Forestali, Università della Basilicata, Potenza, Italy - ¹Entomology & Nematology Department, IACR-Rothamsted, Harpenden, Herts, U.K.

The host recognition and acceptance behaviour of the aphid parasitoid *Aphidius ervi* Haliday is regulated by both chemical and physical cues, and visual cues appear to play an important role (Battaglia *et al.*, 1995, J. Insect Behav., 8, 739-750). Capillary glass tubes sealed on the flame and filled with artificial colours were used to evaluate the oviposition reaction of *A. ervi* females. The highest rate of oviposition reaction was obtained in the yellow region. However, colorimetrically different yellows elicited different ovipositional responses, with a peak value of 95% of reacting females in the case of a chemically defined colour. This spectacular oviposition reaction to colour is being used to develop a technical device for obtaining parasitoid oviposition on artificial diets. However, in natural conditions the oviposition behaviour is also controlled by chemical cues. In fact, both aphid dummies coated with cornicle secretion of the pea aphid, *Acyrtosiphon pisum* (Harris), or exuviae of this host aphid stimulated parasitoid oviposition, which was also observed when the bioassay was carried out under monochromatic red light. This experimental condition, in contrast, totally suppressed the oviposition response on colour filled capillary tubes.

20-137

TELENOMUS BUSSEOLAE (HYMENOPTERA: SCELIONIDAE) EGG PARASITOID OF *SESAMIA NONAGRIODES* (LEPIDOPTERA: NOCTUIDAE) RESPONDES TO SYNTHETIC SEX PHEROMONE IN OLFACTOMETER

M.C. Rosi, A. Clemente, S. Colazza

Agricultural Entomology Institute, Perugia University, Italy

Host olfactory stimuli are important cues during the host location process and the use of host pheromones offers potential in improving the effectiveness of insect parasitoids.

Telenomus busseolae Gahan is an egg parasitoid recently introduced in Italy from Turkey against corn borer *Sesamia nonagrioides* (Lefevre), a serious pest of gramineous crops in the Mediterranean region. The possibility that the synthetic sex pheromone blend has some effect on the host finding behaviour of *T. busseolae* has been investigated.

A four component (Z-11-16:Ac/Z-11-16:OH/Z-11-16:Ald/12:Ac; ratio of 8.5/1/1/2) synthetic sex pheromone blend of the corn borer, commercially available in Italy, has been tested in y-olfactometer as a whole and as single components. Components were used in one of the arms, while the other was the control. Single wasps were introduced into the common arm and observed for 10 min. The first arm entered by the female was scored, the number of visits per arm was counted and the time spent in each of them measured.

Wasps are strongly attracted by the whole blend. The arm containing the odour received a significantly higher number of first choices than the control. In addition the parasitoids spent considerably more time in the test arm.

20-138

ADAPTIVE FORAGING STRATEGIES IN HYMENOPTERAN PARASITES: THE RELATION BETWEEN PARASITOID ECOLOGY AND LEARNING.

Roel P.J. Potting and Louise E.M. Vet

Department of Entomology, Agricultural University Wageningen
PO BOX 8032, 6700 EH, Wageningen, The Netherlands.

For insect parasitoids, learning during foraging is well documented. Host seeking females can learn olfactory and visual cues associated with their hosts or the hosts micro-habitat and experience can strongly affect preference for major foraging cues. Theory on the adaptive value of learning in foraging suggests that an animal foraging in a predictable homogeneous environment and/or making only a few foraging decisions is not expected to use learning in foraging. We studied the role of learning in host foraging in *Cotesia flavipes* (Hymenoptera: Braconidae), a parasitoid of stemborer larvae with an ecology where learning is expected to be of low adaptive value. Using experimental procedures similar to other parasitoid learning studies, we determined the role of the learning mechanisms priming and preference-induction in the foraging of *C. flavipes*. We did not find any evidence that *C. flavipes* uses odour learning in host-microhabitat location. There was no significant effect of the development and emergence environment on the response level or preference towards infested plant odours. Neither did we find evidence that experience with a particular plant-host-complex during foraging influences subsequent foraging decisions in *C. flavipes* females. The absence of learning in *C. flavipes*, which seems an exception among the parasitoids studied, is discussed in relation to its ecology.

20-140

THE POISON GLAND OF THE PARASITIC WASP *Opius concolor* (Hym., Braconidae) CONTAINS REO- AND CORONA-LIKE VIRUS PARTICLESJ.A. Jacas¹, F. Budia², E. Viñuela², E. Rodríguez³, A. Fernández⁴.

¹ Instituto Valenciano de Investigaciones Agrarias. Moncada. Valencia. Spain. ² Protección de Cultivos. E.T.S.I.Agrónomos. Universidad Politécnica. Madrid. Spain. ³ Centro Nacional de Biotecnología. CSIC. Madrid. Spain. ⁴ Centro de Microscopía Electrónica. Universidad Complutense. Madrid. Spain.

Virus-Like particles (VLP) have been found in the poison glands of adult females of *Opius concolor*. The VLP's are found in the secretory cells either free in the cytoplasm or within cytoplasmic vesicles, sometimes associated to a secretory apparatus. Negative staining has revealed the occurrence of two different particles: the first type exhibits a typical morphology of Reovirus-Like particles with a double shelled icosahedral structure (outer diam. 70 nm, inner diam. 60 nm) and hollow surface spikes. The second type was pleomorphic (diameter 30-60 nm) and had an envelope with club-shaped projections as classical Coronaviruses. Function and full characterization of these particles are under way, but it is presumed that they may play a role in the regulation of the tephritid hosts of this wasp, therefore being mutualistic with the latter and parasitic with the flies. It is the first time VLP's isolated from venom glands of a parasitic wasp exhibit either Reo- or Corona-Like viral nature.

20-139

MALE ANTENNAL STRUCTURES OF SOME PARASITOID ACULEATA (HYMENOPTERA) POSSIBLY INVOLVED IN SEXUAL RECOGNITION.P.L. Scaramozzino, G. Pagliano¹, R. Antonelli², N. Isidoro³, F. Bin³.

Museo Regionale di Scienze Naturali, Torino, Italy - 1 Dip. Entomologia e Zoologia applicate all'Ambiente "Carlo Vidano", Università di Torino, Italy - 2 Dip. C.D.S.L., Sezione di Entomologia agraria, Università di Pisa, Italy - 3 Istituto di Entomologia agraria, Università di Perugia, Italy.

Scanning Electron Microscopy observations of male antennae of numerous species of parasitoid Aculeata belonging to several families (Sapygidae, Tiphidae, Mutillidae, Eumenidae, Pompilidae, Sphecidae) have shown the presence of modified cuticular areas, generally hairless, with peculiar sculpture and pores. These areas often correspond to "tyloids" that are considered to be sensory structures. The pores may be the opening of glandular canals, so that further investigation with Transmission Electron Microscopy are in progress to confirm such an hypothesis. These male cuticular areas are probably involved in the chemical stimulation of the female antennal sensilla during mating behaviour, as it happens in some species of parasitoid Parasitica showing similar structures.

The presence of this type of cuticular areas in male antennae of non parasitoid Aculeata, like Vespidae, Anthophoridae and Andrenidae, suggests this phenomenon may concern many more groups of Hymenoptera.

20-141

ANTENNAL SENSORY AND SECRETORY STRUCTURES OF *COPTERA OCCIDENTALIS* MUES. (HYMENOPTERA: DIAPRIIDAE)P. Sacchetti, A. Belcari, N. Isidoro¹, F. Bin¹

Istituto di Patologia e Zoologia forestale e agraria, Università di Firenze, Italy - 1 Istituto di Entomologia agraria, Università di Perugia, Italy

Antennal structures of *Coptera occidentalis* Mues., a Nearctic pupal parasitoid of the walnut fruit fly *Rhagoletis completa* Cress., have been investigated by Scanning and Transmission Electron Microscopes.

Male and female antennal sensilla and glands have been mapped and described. Eight types of sensilla, belonging to aporous, uniporous and multiporous type, have been found.

Aporous sensilla include campaniform type present on the first antennomere or A1 (both sexes), hair plates (probably proprioceptors) located on the proximal and distal margin of A1 (both sexes), trichoid type (some of which tactile) distributed on all the antennomeres (both sexes) and coeloconicum type (probably thermo-hygroreceptor on the lateral side of the A7-A12 in female and on A6-A13 in male).

Uniporous sensilla include only chaeticum type (probably gustatory) present on the ventral side of the A7-A12 in female and arranged in two rings on the A3-A14 in male.

Multiporous sensilla consist of two differently sized sickle-shaped sensilla (probably olfactory) in all antennomeres (except A1-A2) of both sexes and short sensilla basiconica (probably gustatory) present only in female and arranged in patch on the ventral side of A7-A12. Male antennae show two ventral glands on A3 and A4 with different release structures consisting of a peg-like process (A3) and a porous carina (A4).

The possible roles of secretory and sensory structures in mating behaviour and host recognition are discussed.

20-142

COMPARATIVE EXPERIMENTS WITH THE PREDATORY BUGS *ORIU* *INSIDIOSUS*, *O. ALBIDIPENNIS* AND *O. LAEVIGATUS* (HEMPTERA: ANTHOCORIDAE) TO IDENTIFY THE BEST PREDATOR FOR BIOLOGICAL CONTROL OF THE WESTERN FLOWER THRIPS, *FRANKLINIELLA OCCIDENTALIS* (PERGANDE) IN GLASSHOUSE SWEET PEPPERS (*CAPSICUM ANNUUM*).

M. Van de Veire, D. Degheele

Laboratory of Agrozoology, Faculty of Agricultural and Applied Biological Sciences; University of Ghent, Ghent, Belgium.

Two comparative laboratory experiments in which biological parameters of *O. insidiosus* and *O. albidipennis* and *O. albidipennis* and *O. laevigatus* were done, it was concluded that the fecundity of *O. albidipennis* was higher than those of *O. insidiosus*, especially in the beginning of the egg laying period, while the fecundity of *O. laevigatus* was significantly higher than that of *O. albidipennis*. The longevity and fecundity of *O. laevigatus* females were also significantly higher than those of *O. albidipennis* when lacking animal food. The laboratory experiments demonstrated *O. laevigatus* as the best predator for use in IPM programs in glasshouse sweet peppers.

Two comparative glasshouse experiments in commercial sweet peppers in which *O. insidiosus* and *O. albidipennis* and *O. albidipennis* and *O. laevigatus* were simultaneously released for the control of the western flower thrips, *F. occidentalis*, showed that *O. albidipennis* totally replaced *O. insidiosus* and that *O. laevigatus* totally replaced *O. albidipennis* during the experimental period. The glasshouse experiments confirm the earlier found laboratory results very nicely.

20-143

EFFECTS OF FOUR INSECTICIDES ON *ORIU* *LAEVIGATUS* (FIEBER) (HEMPTERA: ANTHOCORIDAE)

L. Tirry, A. De Cock, P. De Clercq, D. Degheele

Laboratory of Agrozoology, Department of Crop Protection, Faculty of Agricultural and Applied Biological Sciences, University of Gent, Gent, Belgium

The anthocorid bug *Orius laevigatus* (Fieber) is widely promoted as an effective biological control agent for the western flower thrips, *Frankliniella occidentalis* (Pergande), a major pest of greenhouse crops. The susceptibility of this predatory bug to the insect growth regulators diflubenzuron and pyriproxifen, the thiourea compound diafenthiuron and the nitroguanidine insecticide imidacloprid was investigated in the laboratory. Toxicity of these compounds by exposure to treated glass plates, by ingestion via treated drinking water and by feeding on surface-treated eggs of *Ephestia kuehniella* Zeller to fifth-instar nymphs and adults of *O. laevigatus* was assessed. Pyriproxifen did not affect the viability of nymphs nor adults. Diflubenzuron was harmless to adults, but toxic to nymphs by residual contact (LC₅₀: 391 mg a.i./l) or by ingestion via drinking water (LC₅₀: 230 mg a.i./l). Diafenthiuron was more toxic to adults (LC₅₀: 100 mg a.i./l) than to nymphs (LC₅₀: 329 mg a.i./l) by residual contact, but harmless by ingestion via drinking water and by feeding on treated *Ephestia*-eggs. Imidacloprid had adverse effects on the survival of nymphs and adults of the predator, whatever the method of exposure (e.g. LC₅₀: 0.65 mg a.i. /l for adults after residual contact). Preliminary results show that even systemically applied imidacloprid is highly toxic to *O. laevigatus* wandering on the leaf surface.

These results indicate that integrated pest management programmes involving diflubenzuron, diafenthiuron and imidacloprid should regard possible side-effects to this beneficial insect.

20-144

EFFECT OF SOME INSECT GROWTH REGULATORS ON THE PREDATORY BUGS *ORIU* *LAEVIGATUS* (FIEBER) (HEMPTERA: ANTHOCORIDAE)

G. Angeli, D. Forti, R. Maines,

Istituto Agrario San Michele all'Adige (Tn), Italy

Laboratory trials were carried out in order to test the effectiveness of seven insect growth regulators (tebufenozide, fenoxycarb, esafumuron, buprofezin, alsystin, teflubenzuron and diflubenzuron) on *Orius laevigatus* (Fieber). The insecticides were administered by contact at concentrations recommended for agricultural use.

The results with regard to the number of living adults obtained from 4 th (20%) and 5 th (80%) instars larvae, after exposure to fresh spray pesticides deposit on glass Petri dishes for 7 days, showed that all products but for esafumuron had no appreciable effect. Esafumuron slightly affected the development of immature stages into adults (63.3% mortality Abbott).

This treatments did not have any sensible influence on the number and on the eggs fertility of females obtained from 4 th and 5 th instars of treated larvae.

When treated with the five inhibitors of chitin synthesis esafumuron, buprofezin, alsystin, teflubenzuron and diflubenzuron, none of the 1 st (50%) and 2 nd (50%) instar larvae, after exposure to fresh spray pesticides deposit, developed into adults.

The experimental trial proves that the contact activity of the juvenile hormone mimic fenoxycarb and the ecdysis hormone mimic tebufenozide is approximately that of the inhibitors of chitin synthesis used.

20-145

SUPER-COOLING POINT IN ADULTS OF *ORIU* *SAUTERI* AND *O. MINUTUS* (HEMPTERA: ANTHOCORIDAE).

K. Ito, T. Nakata, J. Kaneko

Hokkaido National Agricultural Experiment Station, Hitsujigaoka, Sapporo, Hokkaido, Japan

Orius species are known as important natural enemies attacking agricultural pests such as thrips, mites or aphids. *O. sauteri* and *O. minutus* are most common in Japan and they overwinter as adults. However, only females can survive until the next spring. Males are likely to have low cold hardiness. Since the overwintered females are already mated, they are able to lay fertile eggs without males in spring. To elucidate the cause of sexual difference of such hibernating success, we compared super-cooling point (abbr. SCP) of the adults, because SCP is one of the good indicator of cold hardiness in insects.

SCP of the diapausing adult (grown under 16L-8D regime at 25°C) of *O. sauteri* was -24.7±2.3 days (N=30) in the female and -21.7 ±2.4 days (N=39) in the male. It indicates that the diapausing male has considerably low SCP, though the diapausing female has statistically lower SCP. A similar result was obtained in diapausing adults of *O. minutus*; SCP was -22.9 ±2.6 days (N=36) in the female and -22.3±2.7 days (N=35) in the male.

Since the lowest winter temperature seldom falls below -15°C in Sapporo, SCP of the diapausing males of both species seems to be enough to tolerate freeze. In conclusion, there are no biological differences in SCP between the sexes in both species. Factor(s) other than SCP may affect the sexual difference of winter survival.

20-146

DIFFERENTIAL NUTRIENT ALLOCATION TO REPRODUCTION AND SOMATIC MAINTENANCE BETWEEN TWO SPECIES OF *Orius* (HETEROPTERA: ANTHOCORIDAE)**Yoshitaka Nakashima and Yoshimi Hirose****Institute of Biological control, Faculty of Agriculture, Kyushu University, Fukuoka, Japan**

A laboratory experiment was conducted to determine the effects of egg production on the longevity of females of *Orius sauteri* and *O. tantillus*, predators of *Thrips palmi*. We compared their longevity between unmated and mated females because oviposition of both *Orius* species occurs only among their mated females. The results of the experiment showed that in *O. sauteri*, the longevity of mated females was half as much as that of unmated females, but that there was no difference in the longevity between mated and unmated females of *O. tantillus*. Daily fecundity of *O. sauteri* was twice as much as that of *O. tantillus*. It follows that egg production of *O. sauteri* results in a shortened longevity, whereas egg production of *O. tantillus* does not, and that the allocation of nutrients to reproduction and somatic maintenance differs between these two species. It is concluded that *O. sauteri* invested nutrients more heavily in its reproduction than *O. tantillus*.

20-148

HETEROPTEROUS PREDATORS OF THE PEAR PSYLLA (*CACOPSYLLA PYRI*) IN EASTERN SICILY**C. Rapisarda¹, S. Beninato², G. Campo²****1 Istituto di Entomologia agraria, Università degli Studi, Catania, Italy - 2 Osservatorio per le Malattie delle Piante, Acireale, Italy**

The Authors deal with the first results of a study which has been recently started on the arthropod fauna limiting the pear psylla (*Cacopsylla pyri*) populations, in a wide fruit area on the western slopes of Mount Etna. In particular, data are reported here on the activity of predacious Heteroptera, deriving from regular collections made by the method indicated as "battage" or "frappage", in various orchards where different pest management schemes were adopted. Emphasis has been given to the general study of the involved biocenosis, which showed the constant and predominant occurrence of *Anthocoris nemoralis*, compared to the other representatives of both the families Anthocoridae and Miridae. Comments are also given on the catches of all the species, in relation to the seasons, to the population trend of the pear psylla and the phytiatric management of the orchards.

FEEDING ACTIVITY, DEVELOPMENT AND REPRODUCTION OF *Orius majusculus* REUTER EXCLUSIVELY FED WITH *Thrips tabaci* LINDEMAN**C. Sengonca and M. Schade****Institute of Phytopathology, University of Bonn, FRG**

The polyphagous predatory bug *Orius majusculus* Reuter (Het., Anthocoridae) is a commercial product primarily sold for greenhouse use. Laboratory studies were conducted to determine its suitability for use as a predator against the important pest *Thrips tabaci* Lindeman (Thys., Thripidae) on field grown leek, onion and cabbage. Feeding activity, development and reproduction were studied in specially prepared bioassay chambers, that provided hiding places for the thrip larvae (L₂). All experiments were carried out with a fluctuating temperature of 24±1 °C and 17±1 °C at 16 h of artificial illumination and 8 h of darkness.

Female L₅-larvae showed the highest predatory activity with an average of 4.7 thrips larvae consumed per day. Male L₅-larvae only consumed 4.2 thrips larvae per day. Adult feeding activity was slightly lower. More than 400 thrips were consumed during the life cycle of a female bug. Complete female development took an average 51.6 days and the males 45.4 days. Almost 70 % of the predatory bugs developed fully on *T. tabaci*. The females of the first generation which had been fed exclusively on *T. tabaci*, laid 92.6 eggs during their oviposition period. The females of the F₁-generation, which had been exclusively fed with thrips, also achieved a significantly higher egg production level. They laid (?) An average of 131.0 eggs during the same oviposition period.

20-149

THE USE OF SPECIES *PODISUS MACULIVENTRIS* (SAY) (HETEROPTERA : PENTATOMIDAE) FOR BIOLOGICAL CONTROL OF COLORADO BEETLE IN THE POTATO CROPS FROM ROMANIA**T. MANOLE, M. IAMANDEI¹****Department of Entomology, Research Institute for Plant Protection, Bucharest, Romania-1Department of Entomology, Research Institute for Plant Protection, Bucharest, Romania**

In the present paper are included for the first time in Romania data concerning the use of species *Podisus maculiventris* (Say) in the biological control of larval density of Colorado beetle population in the potato crops including the four important agricultural regions from Romania.

The experimental dispositive was composed by 4 variant which are corresponding at the different levels of spreading. The results obtained are presented in the tables and shows a good efficiency in the control of the pest in comparison with the chemicals standard.

20-150

POSSIBILITIES OF BIOLOGICAL CONTROL OF NOCTUID EGGS BY THE MIRID *CYRTOPELTIS TENUIS* REUTER (HETEROP.: MIRIDAE).

M. Hernández García, R. Torres del Castillo, L. Rumeu Ucelay, E. Hernández Suárez, F. Pérez Padrón, A. Carnero Hernández.

Departamento de Protección Vegetal, Instituto Canario de Investigaciones Agrarias, La Laguna, Tenerife. Islas Canarias, España.

Periodical observations about the population dynamic of *Cyrtopeltis tenuis* were carried out on out-door tomato crops in Tenerife Island. The results showed a very good control of the noctuid *Autographa gamma* (Lep.: Noctuidae) eggs by the mirid and the correlation between the vertical and spatial distribution of both factors, mirids and eggs.

20-152

PHEROMONE-INDUCED MOVEMENT OF *Podisus maculiventris* (HETEROPTERA: PENTATOMIDAE) NYMPHS

J. Sant'ana, R. Bruni¹, J.R. Aldrich²

Universidade Federal do Rio Grande do Sul. Faculdade de Agronomia, Departamento de Fitossanidade. Porto Alegre, RS, Brazil -1 Istituto di Entomologia Agraria, Università di Perugia, Italy -2 Insect Chemical Ecology Laboratory USDA-ARS Beltsville, MD USA

Field experiments were conducted at USDA (Beltsville, MD, USA) during the summer of 1995. The pheromone-induced movement of nymphs of the generalist predator spined soldier bug (*Podisus maculiventris* (Say) (Heteroptera: Pentatomidae), was determined by using pheromone releasers. The experimental field was planted with green beans (*Phaseolus vulgaris*), and divided in seven plots of 13 rows each. When the plants were three weeks old, plots were already naturally infested with Mexican bean beetles (*Epilachna varivestis* (Moulsant) (Coleoptera: Coccinellidae)), a common prey of *P. maculiventris*. At that time, third and fourth instars of the Spined soldier bug were released in the seventh row, and three pheromone releasers were placed outside the thirteenth row of each plot. The movement of the nymphs in either direction (i.e. towards the pheromone releasers or in the opposite direction) was determined three times in the lapse of one week. Results did not show nymphal movement 24 hours after release. However, the observations conducted in the fourth and seventh day after release showed a significant movement of the pentatomids in the direction of the pheromone releasers.

20-151

KAIROMONAL ACTIVITY OF AGGREGATION PHEROMONE IN THE SYSTEM *Podisus maculiventris* (SAY)- *Telenomus* spp. (HETEROPTERA: PENTATOMIDAE; HYMENOPTERA: SCELIONIDAE)

R. Bruni¹, J. Sant'ana², J. R. Aldrich³, F. Bin¹

1 Istituto di Entomologia Agraria, Università di Perugia, Italy -2 Universidade Federal do Rio Grande do Sul. Faculdade de Agronomia, Departamento de Fitossanidade. Porto Alegre, RS, Brazil -3 Insect Chemical Ecology Laboratory USDA-ARS Beltsville, MD USA.

The kairomonal activity of the aggregation pheromone of *Podisus maculiventris* (Say), a predacious stink bug, has been tested in the field with two egg parasitoids, the Scelionids *Telenomus calvus* Johnson a specialist phoretic species, and *Telenomus podisi* Ashmead a generalist non-phoretic species.

Egg masses of *P. maculiventris*, obtained from a laboratory culture, were placed in traps (plastic cylinders with two funnel openings) baited with synthetic pheromone and exposed in the field. The egg masses of a phytophagous Pentatomid, *Euschistus obscurus* (Palisot), were also placed in the same traps to test the possible effects of the pheromone on acceptance behavior of both parasitoids. Traps of the same type with egg masses and without pheromone were used as controls. The traps were checked twice a week, rebaited and reloaded with freshly laid egg masses for about three months. The *P. maculiventris* population was monitored using the same traps from early spring.

Parasitized vs. unparasitized egg-masses were checked in the laboratory to assess the location and exploitation efficiency of the two *Telenomus* species. *T. podisi* did not respond to the pheromone whereas *T. calvus* was attracted by it and was capable of successfully attacking the host eggs without the phoretic phase, i.e. with no contact with the adult host.

The possibility of using the pheromone to manipulate the predator, when introduced in new environments, is discussed.

20-153

PREY DEFENSES AFFECT THE PREY PREFERENCE OF THE PREDATORY BUG, *Eocanthecona furcellata* (WOLFF) (HETEROPTERA: PENTATOMIDAE: ASOPINAE)

Mitsutaka Sakakibara

Japan International Research Center for Agricultural Sciences (JIRCAS), Ishigaki, Okinawa 907, Japan

An asopine bug, *Eocanthecona furcellata*, is an effective predator of many insect pests in the Orient. The prey preference of *E. furcellata* was investigated with 71 insect species as prey, and it was found to be affected by some characteristics of the prey. *E. furcellata* tended to prefer the species that wandered extensively, had weak defences, a soft skin, no smell, no poisonous substance(s), and no projections, as compared to species stopped moving rapidly, had strong defenses, a hard skin, projections, a noxious odor, and/or a poison(s). From scores for these defensive characteristics of the prey, a simple discriminative index of the suitability for the predator in a closed environment is proposed for use in attempts at biological control. This study also provides some new host records for *E. furcellata* in Japan.

20-154

ROLE OF THE CHEMICAL CUES IN THE LARVAE OF *SPODOPTERA LITURA* IN PREY-LOCATION BEHAVIOR OF THE PREDATORY STINK BUG, *EOCANTHECONA FURCELLATA*.

T. Yasuda, S. Wakamura

Department of Insect Physiology and Behavior, National Institute of Sericultural and Entomological Science (NISES), Ohwashi 1-2, Tsukuba, Ibaraki 305, Japan

Behavioral responses of a predatory stink bug, *Eocanthecona furcellata* (Wolff) (Heteroptera: Pentatomidae) towards *Spodoptera litura* (Fabricius) (Lepidoptera: Noctuidae) larvae were observed in olfactometers. In dual-tube olfactometer, adult bugs were observed to approach and stretch the proboscis toward the air containing odors from intact *S. litura* larvae. The solvent extracts of larvae elicited similar behaviors. In a linear track olfactometer, nymph bugs were observed to be attracted to a fraction from silica gel column chromatography, but proboscis-protruding behavior was not observed toward this fraction. The proboscis-protruding behavior was, however, observed toward the other fraction by simple behavioral assay using a Pasteur pipette. These findings therefore indicated the presence of at least two different chemical cues in prey-location.

20-156

APHELINUS SPECIES (HYMENOPTERA: APHELINIDAE), PARASITOIDS OF APHIDS (HOMOPTERA: APHIDIDAE) IN EUROPE

V.A. Yasnosh, O.A. Chervonenko¹

Department of Biological Control, Kanchaveli Plant Protection Research Institute, Tbilisi, Republic of Georgia, - 1 Department of Taxonomy and Entomophagous Insects and Ecological Principles of Biological Control, Institute of Zoology, Kiev, Ukraine

The species of genus *Aphelinus* Dalman are known almost exclusively as primary endoparasitoids of aphids and are of importance in control of these pests.

Aphelinus species from European part of Palaearctic are revised, including the new materials. Twenty two species are recorded. Five species are recorded for the first time. Three of these: *Aphelinus brunneus* Jasnosh, *A. campestris* Jasn., *A. lucidus* Jasn., were earlier described from other parts of Palaearctic and two species - *A. fuscus* Chervonenko, *A. coracinus* Chervon. are described as new.

Notes on taxonomy, distribution, host range are discussed.

20-155

DEVELOPMENT OF *MACROLOPHUS CALIGINOSUS* AND *DICYPHUS ERRANS* REARED ON DIFFERENT DIETS (RHYNCHOTA MIRIDAE)

L. Tavella, A. Arzone

Dipartimento di Entomologia e Zoologia applicate all'Ambiente "Carlo Vidano", Università di Torino, Italy

The presence of several species of Miridae Dicyphinae has been checked in IPM vegetable crops in South Europe during the last years. These species, considered polyphagous predators and characterized by a zoophytophagous behaviour, were able to control whitefly infestations. In northwestern Italy the most abundant species were *Macrolophus caliginosus* Wagner and *Dicyphus errans* (Wolff).

In order to study the zoophytophagous behaviour and to ascertain the survival rate and the postembryonic developmental period of these two species, they were reared on three different diets: animal (eggs of *Ephestia kuehniella* Zeller), vegetal (French bean pods), mixed (eggs + pods), and at two temperatures: T1 (18-22°C), T2 (22-26°C). For each diet and each temperature, 15 specimens of the two mirids were reared in glass tubes and were daily checked.

M. caliginosus was able to complete its development on all diets, nevertheless it showed the highest rate of emergences on the mixed diet at both temperatures. On the contrary, *D. errans* was unable to survive on the vegetal diet, whereas it completed the egg to adult development when reared on the other two diets; the higher rate of emergences was observed on the mixed diet at both temperatures.

The postembryonic developmental period was influenced by diet and temperature in both species. Nymphs of *M. caliginosus* reared on the vegetal diet took a significantly longer time from hatching to emergence (50±6.66 days at T1 and 29.9±4.82 days at T2) than nymphs reared on the other two diets (from 31±2.94 days on the animal diet at T1 to 22.8±1.85 days on the mixed diet at T2). Nymphs of *D. errans* reared on animal and mixed diets became adults in significantly different times: longer on the animal diet (32±2.4 at T1 and 17.5±2.66 at T2) than on the mixed diet (28.5±2.32 at T1 and 15.5±1.36 at T2).

The mixed diet appeared the most suitable nourishment for rearing both species.

20-157

FAUNA OF APHELINIDS (HYMENOPTERA: APHELINIDAE) IN THE MOUNTAINOUS FRUIT ORCHARDS IN REPUBLIC OF GEORGIA

G. Japoshvili, V. Yasnosh¹

Department of Invertebrate Animals, Institute of Zoology, Tbilisi, Republic of Georgia - 1 Department of Biological Control, Institute of Plant protection, Tbilisi, Republic of Georgia

Fruit orchards are on the south slopes of Caucasus. The principal are apple, pear and plum cultures.

The distribution of aphelinids is connected with their main hosts: coccid insects (Homoptera: Coccinea) and aphids (Homoptera: Aphidoidea). On 18 species of armored scales (Diaspididae) 13 species of aphelinids are registered, predominantly from the genera: *Aphytis* (5), *Encarsia* (2) and *Coccobius* (1). They are of importance in the control of *Diaspidiotus perniciosus* (Comstock), *Parlatoria oleae* (Colvée), *Epidiaspis leperii* (Signoret) and other pests.

For the control of Coccidae family pests (4) are more important: *Coccophagus palaeolecanii* Jasnosh and *C. lycimnia* (Walker).

More than 20 species of aphids and only 4 species of aphelinids, there parasitoids, are known in fruit orchards. More common are *Aphelinus mali* (Haldeman) and *A. chaonia* (Walker).

The fauna of aphelinids forms predominantly by European species and only some Asiatic species are here distributed.

The list of the Aphelinidae species and their hosts is presented.

20-158

PARASITIDS (HYMENOPTERA: CHALCIDOIDEA) AS BIOLOGICAL CONTROL AGENTS FOR THE WHITEFLY ALEUROCYBOTUS INDICUS DAVID & SUBRAMANIAM (HOMOPTERA: ALEYRODIDAE) ON RICE IN CHINA

J. Huang

Department of Plant Protection, Fujian Agricultural University, Fuzhou, Fujian, P.R.China

The whitefly of rice was first found in China in 1960, when it was identified as Bemisia sp. It is obvious that specimens of the whitefly of rice examined from Fujian Province of China are Aleurocybotus indicus David & Subramaniam. The whitefly of rice has recently become an important pest and is spreading to many other rice-growing areas in China.

Three parasitoids on the whitefly of rice have been found, in which Encarsia japonica Viggiani and Encarsia transvena (Timberlake) are dominant parasitoids with high percentage of population, and another species of Eulophidae is with very low population. Parasitism by the two species of Encarsia is generally in 6.68-33.04%, and 13.38% on an average. Parasitoid population reaches its peak in mid July and from late August to early September. Encarsia spp. are expected to be used as biocontrol agents for the whitefly of rice.

20-160

REPRODUCTIVE BIOLOGY AND MORPHOLOGY OF AN APHELINID PARASITOID ATTACKING THE SILVERLEAF WHITEFLY.

D. H. Headrick, T. S. Bellows, & T. M. Perring

Department of Entomology, University of California, Riverside, California, USA

The reproductive biology and the morphology of the reproductive system of Eretmocerus sp. nr. californicus that attacks silverleaf whitefly, Bemisia argentifolii Bellows & Perring are described. Ova morphology of Eretmocerus and Encarsia species is compared.

Demographic parameters such as fecundity, fertility, longevity, reproductive rates, and intrinsic growth rates are described for Eretmocerus sp. nr. californicus. Aspects of parasitoid oviposition behavior for E. sp. nr. californicus was analyzed on five host plant species. Adult wasps reared on sweet potato showed major differences in overall reproductive output of parasitoids exposed to different host plant species with differing leaf morphology. The most significant behavioral differences were the willingness of adult parasites to remain and search for whitefly hosts and the durations of host assessment and host feeding were also strikingly different among the host plant species.

The effects of the natal host plant on parasitoid searching and selection behaviors and percentage oviposition were tested and analyzed. Wasps raised on melon rather than sweet potato showed no significant differences in their performance on that host plant or the other plants species tested.

20-159

PARASITIDS (HYMENOPTERA, CHALCIDOIDEA) OF WHITEFLIES (HOMOPTERA, ALEYRODOIDEA) IN TURKMENISTAN
S.N.Myartseva

Institute of Zoology, Academy of Sciences of Turkmenistan, Ashgabat, Turkmenistan

At present in Turkmenistan are revealed 14 species of whiteflies. There are by our investigations 10 reliable parasitoid species of aleyrodids in Turkmenistan. They are belonging to 3 families of chalcidoid wasps: Aphelinidae (7), Eulophidae (2) and Encyrtidae (1 species). Hosts of these parasitoids are 8 whiteflies species. 5 species from them were not known before in Turkmenian fauna, including 4 species what were not known in Central Asia too.

Parasitoid's lists of main pests include: 6 species for Bemisia tabaci Genn., 5 species for Trialeurodes vaporariorum Westw. There are mainly species of genera Encarsia and Eretmocerus in these complexes. In conditions of Turkmenistan preferable hosts are: by Eretmocerus nikolskajae Myarts.- Bulgarialeurodes cotesi Mask., by Eretmocerus mundus Merc.- Bemisia tabaci, by Encarsia inaron How.- Aleyrodes proletella L.

20-161

INTRA- AND INTERSPECIFIC HOST DISCRIMINATION IN COCCOBIUS FULVUS (COMPERE ET ANNECKE) (HYMENOPTERA: APHELINIDAE), A PARASITOID OF UNASPIS YANONENSIS

N. Sugiura, M. Takagi

Institute of Biological Control, Faculty of Agriculture, Kyushu University, Hakozaki, Fukuoka, Japan

Coccobius fulvus and Aphytis yanonensis were introduced parasitoids from China to Japan for the biological control of the arrowhead scale, Unaspis yanonensis. To determine ability of intra- and interspecific host discrimination of C. fulvus, an intrinsically inferior species, oviposition behavior of the females toward hosts containing different developmental stages of conspecific and A. yanonensis were observed. They rejected hosts containing eggs, young larvae, old larvae and pupae of conspecific at 66.7, 20.0, 72.7 and 100%, respectively. The rejection of hosts containing eggs of conspecific was occurred before probing but the parasitoid rejected the hosts containing larvae or pupae after probing. It was suggested that the females used external cues to discriminate hosts with parasitoid eggs but they used internal ones when the hosts contained parasitoid larvae and pupae. On the other hand, the females rejected hosts containing eggs, young larvae, old larvae and pupae of A. yanonensis at 0, 25.0, 100 and 100%, respectively. It seemed that the external cues could not be detected by C. fulvus when the hosts had been parasitized by A. yanonensis. After the rejection of the hosts parasitized by A. yanonensis, 29% of the females fed from the host. The rejection of the hosts and the feeding from them could be adaptive behavior because C. fulvus was defeated in the case of multiparasitism.

20-162

NATURAL ENEMIES OF APHIDS AND THEIR POTENTIAL POWER IN TÜRKİYE

Z.Yoldaş, C.Öncüler¹

Ege University, Faculty of Agriculture, Department of Plant Protection, 35100 Bornova, İzmir, Türkiye

¹ Adnan Menderes University, 09100, Aydın, Türkiye

Aphids are one of the most destructive agricultural pests and can cause significant damages direct or indirect ways for plants. However, the family of Aphididae (Homoptera) has also several natural enemies. Many studies have been done about the natural enemies of aphids by various entomologists in Türkiye. In the present study, all the previous records concerning the predators, parasitoids and diseases of aphids were compiled and listed.

In Türkiye 162 predatory insects in Coleoptera, Diptera, Neuroptera and Heteroptera orders, 38 parasitoids in Aphidiidae, Aphelinidae, Encyrtidae, Pteromalidae families (Hymenoptera) and an entomopathogen fungus were determined. In addition to the mentioned natural enemies 10 hyperparasite species and 19 parasite of the predators were found out. In the remaining part of the article certain knowledge on the potentiality of these beneficial insects was discussed.

20-164

SUCCESSFUL BIOLOGICAL CONTROL OF *Parabemisia myricae* (KUWANA) BY *Eretmocerus debachi* ROSE ET ROSEN IN THE EAST MEDITERRANEAN CITRUS-REGION OF TURKEYÇ. Şengonca¹, N. Uygun², U. Kersting², M.R. Ulusoy²¹Inst. of Phytopathology, University of Bonn, FRG and ² Dept. of Plant Protection, University of Çukurova, Turkey

The White Fly, *Parabemisia myricae* (Kuwana) (Hom., Aleyrodidae), which had been imported in the mid eighties, is a serious pest of citrus because of direct feeding damage as well as for its role as vector of citrus chlorotic dwarf (CCD) a severe disease in the east Mediterranean region of Turkey. To control this pest biologically, the aphelinid *Eretmocerus debachi* Rose et Rosen (Hym., Aphelinidae) was imported and mass released in the entire citrus-growing area. Within only three years the whitefly population was brought down to almost zero level. Even to smallest increases in pest populations, the parasitoid reacted with increasing parasitization. The high efficiency of *E. debachi* was also proved in laboratory experiments. The developmental time ranges from 12-28 days and the longevity lasted 2.1-3.7 days. Thus, *E. debachi* completed 13-14 generations a year while *P. myricae* passes only 7-8. *E. debachi* reproduced thelytokously, parasitizing about 53 individuals of different *P. myricae*-instars. A high mortality of *P. myricae* occurred due to host-feeding. The total mortality (parasitization and host-feeding) reached about 97 % for *P. myricae*-second instar nymphs. The biological control of *P. myricae* by *E. debachi* was a complete success and is one of few outstanding examples in biological control of whitefly species.

20-163

APHID-ATTACKING APHELINID SPECIES IN JAPAN: TAXONOMY, BIOLOGY AND BEHAVIOR.

H. Takada

Laboratory of Entomology, Faculty of Agriculture, Kyoto Prefectural University, Kyoto, Japan
Two species of *Aphelinus* have hitherto been recorded from Japan. In the present study 13 other species are added to the fauna. These species are outlined and some information on their biology, and oviposition and host-feeding behavior is given. Discussion on the generic taxonomy will also made.

20-165

NATURAL ENEMIES OF WHITEFLIES IN THE DOMINICAN REPUBLIC - THEIR PROSPECTS FOR BIOCONTROL IN TOMATO AND ORNAMENTAL CROPS

C.A. Serra, M. Ortiz, J.B. Nuñez, A. Schulz² & P. F. BenoitProyecto 'Mosca Blanca', Instituto Superior de Agricultura (ISA), Apartado 166, Santiago de los Caballeros, Dominican Republic; ² Fachhochschule Weihenstephan, Freising, Germany

The Dominican mainly processing-tomato production in the irrigated lowlands has been severely threaten since 1988/89 by excessively high and insecticide-resistant populations of *Bemisia tabaci* and since 1991 by the transmission of geminiviruses as the tomato yellow leaf curl virus (TYLCV-Is). In order to enhance biocontrol as a component of IPM of the *Bemisia tabaci* complex and also *Trialeurodes vaporariorum* (in vegetables incl. fresh market tomatoes in mountain valleys), a nationwide survey on existing whitefly species (≥ 18 spp.) and associated enemies was carried (1995-96). Their potential for biocontrol mainly during the crop-free period is discussed.

Coccinellids (incl. *Delphastus*, spp.), chrysopids and other predators were recorded, but only mind bugs (*Cyrtopeltis tenuis*, *C. modesta*) occur in relative high densities after the critical initial weeks. Although natural parasitism is relatively low in existing tomato-growing systems, a diversity of parasitic aphelinids incl. *Encarsia transvena*, *Encarsia* sp. (*parvella* group, uniparental?), *En. pergandiella*, *En. formosa*, *En. meritoria*. (= *?hispidia*), *En. nigricephala* and *Eretmocerus* sp. nr. *californicus* have been reared from weeds and crops. *A. fuscipennis* (Hym.: Platygasteridae) a parasitoid of *T. vaporariorum* shows high parasitism levels ($\leq 95\%$) in unsprayed plants in mountain valleys. Endemic species have been compared in bioassays and field cages to biotypes imported from MBCC, Mission, Texas, in order to start mass rearing and liberation of the most promising parasitoids. Entomopathogenic fungi (Hyphomycetes-Moniales) *Paecilomyces fumoso-roseus* and *Verticillium lecanii* (≤ 500 and 400-1500 m.a.s.l. respectively) occur associated to *T. vaporariorum*. Commercial mycoinsecticides as well as selected endemic and introduced strains of different fungi species (incl. of *Beauveria bassiana*, *Entomophthora virulans*) were compared on tomato and *Gerbera* sp. plants.

20-166

COMPARISON OF SEARCHING EFFICIENCIES OF FIVE PARASITOID SPECIES (APHELINIDAE AND PLATYGASTERIDAE) OF *BEMISIA TABACI*/ARGENTIFOLII (ALEYRODIDAE).

Y.C. Drost, C.J.A.M. Posthumus-Doodeman, J.C. van Lenteren
Department of Entomology, Agricultural University Wageningen, Netherlands.

The first step in the selection of natural enemies for biological control is an evaluation based on qualitative parameters: seasonal synchronization with host; internal synchronization with host; climatic adaptation; no negative effects such as hyperparasitization; easy to rear. The second step is to rank these species with respect to their efficiency to depress the host and when inoculative control is intended to maintain the host below the economic threshold level. Searching efficiency is one of the factors that is hypothesized to be important for the efficiency of natural enemies in biological control, specifically at the low host densities occurring around the economic threshold level. For five parasitoid species of *Bemisia tabaci*/argenteofolii: *Encarsia formosa* Gahan (Aphelinidae), *Amitus bennettii* Viggiani & Evans (Platygasteridae); *Eretmocerus* nr *californicus* (Aphelinidae); *Er. mundus* Mercet. and a uniparental *Er. sp.* from Texas, we determined the walking speeds and walking patterns on poinsettia (*Euphorbia pulcherrima*, cv. Goldfinger) leaf discs before and after encounter of a host larva and before and after encounter of honeydew of the host. Data were recorded using a sampling rate of 8 frames per second with an automated system that directly translates the video picture into digital information. When no host cues are used, we expect random turning and no area restricted search. In this case the probability of encountering a host depends very much on the walking speed and the innate turning rate of the parasitoid. When host cues are used we expect some kind of area restricted search in case of contact infochemicals and directed search in case of volatile infochemicals. We will present the data for these species on the walking speed and walking pattern (amount of turning, amount of looping, number of times crossing its own path) and rank the species based on these parameters. Whether the ranking of the parasitoids at the level of the individual behaviour is also reflected in their efficiency at the population level will be evaluated using the simulation model developed in our laboratory.

20-168

BIOLOGY AND BIOCONTROL POTENTIAL OF *PEDIOBIUS FURVUS* (GAH.) FOR THE MANAGEMENT OF CEREAL STEM BORERS IN AFRICA.

A.H. Duale

International Crops Research Institute for the Semi-Arid Tropics (ICRISAT), Patancheru 502 324. Andhra Pradesh, India.

Pediobius furvus (Gah.) (Hymenoptera: Eulophidae) is a gregarious endoparasitoid of graminaceous stem borers in Africa. Investigations on the nature of trophic interactions between the plant, host insect and the parasitoid showed that no one stimulant alone performed the service of guiding *P. furvus* females to their proper host habitat, and the host location is achieved by a complex of array of stimuli working in harmony. Studies in the laboratory showed that low temperature resulted in longer developmental period, less progeny production and preponderance of males. Host and parasitoid age independent of size, were found to be one of the most important factors influencing the acceptability and suitability of both *C. partellus* and *B. fusca* pupae. Sucrose and/or honey concentrations as food for the adult parasitoid has played an important role in prolonging the longevity of the adult parasitoid but does not affect its fecundity. Studies on oviposition and through dissections reveal that the parasitoid is pro-ovigenic. Superparasitism in this parasitoid is accompanied by a reduction in size of the adult and preponderance of males which reduce the efficacy of the parasitoid. The rate of multiplication of *P. furvus* in one generation was found to be 335 and the mean length of the parasitoid generation recorded was 21 days. The species has a finite rate of increase as 1.31 per day at 25 ± 10 °C under 65 ± 1.5% RH.

20-167

PARASITIDS REARED FROM APHIDS ATTACKING CITRUS AND THEIR FREQUENCY IN GREECE

N. Kavallieratos and D. Lykouressis

Laboratory of Agricultural Zoology and Entomology, Agricultural University of Athens, Athens, Greece

A study concerning the knowledge on parasitoids, which attack aphids infesting various citrus, was undertaken since the spring of 1995 over the most important citrus growing areas of Greece. The samples taken were kept in suitable conditions to allow emergence of parasitoids from the aphid mummies, and then specimens were identified using appropriate keys.

The study revealed the presence of several parasitoid species belonging to genus *Aphidius*, *Trioxys*, *Lysiphlebus* and *Diaeretiella* (Hymenoptera, Aphididae). The parasitoids found emerged from various aphid species such as *Aphis spiraeicola* Patch, *Aphis gossypii* Glover, *Toxoptera aurantii* (Boyer de Fonscolombe) and *Myzus persicae* (Sulzer). *A. gossypii* was found to be parasitized by the most parasitoid species recorded whereas *Aphidius colemani* Viereck parasitized all aphid species which developed colonies on various citrus.

Distribution of Parasitism by *Lydella thompsoni* (Hert.) (Diptera: Tachinidae) in Maize Attacked by Stalk Corn Borer, *Sesamia nonagrioides* Lef. (Lepidoptera: Noctuidae)

Diogo Figueiredo
Jorge Araújo

University of Evora
Department of Biology
Aparado 94 - 7001 Evora codex
Portugal

Abstract

Lydella thompsoni (Herting) (Diptera: Tachinidae) is a parasitoid of the stalk corn borer, *Sesamia nonagrioides* Lef. (Lepidoptera: Noctuidae). Over a 2-yr period, we collected stalk corn borer larvae from maize fields in Sorraia Valley (South of Portugal) to determine how host density and other factors influence the distribution of parasitism. The proportion of parasitized larvae was density dependent at the single-stalk and fields scales. Parasitism was always higher only in the 2nd generation of the trivoltine population. Proportion of parasitized larvae was correlated with the frequency of infested stalks. These relationships suggest that searching and oviposition (i.e. foraging) by the parasitoids may be among the maize stalks infested. The apparent efficiency of *L. thompsoni* in the 2nd generation of *S. nonagrioides* is discussed.

Key Words- *Lydella thompsoni*, *Sesamia nonagrioides*, biological control.

ECOLOGICAL AND GENETIC INTERACTION BETWEEN AN INTRODUCED AND AN INDIGENOUS TORYMID PARASITOID IN BIOLOGICAL CONTROL OF THE CHESTNUT GALL WASP

K. Yara, E. Yano, M. Shiga¹

Division of Entomology, National Institute of Agro-Environmental Sciences, Tsukuba Ibaraki, Japan -1 Department of Insect Physiology and Behavior, National Institute of Sericultural and Entomological Science, Tsukuba Ibaraki, Japan

The chestnut gall wasp is assumed to have been introduced from China around 1940. *Torymus sinensis* was introduced from China into Japan and released at Tsukuba in 1982 for controlling this pest. After establishment, the parasitoid spreaded gradually in the Kanto Plains and caused a considerable reduction of the density of galls of the wasp. Before the introduction of *T. sinensis*, a closely related species, *T. beneficus*, was known to be an indigenous parasitoid of the wasp. Galls of the wasp were collected at several sites of the Kanto Plains and emerged adults of torymid parasitoids from the galls were checked for several years. As a result, it is likely that *T. beneficus* is being excluded by *T. sinensis* in this area. Isozyme discrimination was carried out to confirm possibilities for occurrence of interspecific crossing in the field between the two torymid species. The results suggest a low rate of interspecific crossing although hybrid individuals were produced in crossing experiments.

20-172

CLASSICAL AND FORTUITOUS BIOLOGICAL CONTROL WITH ENTOMOPHAGOUS INSECTS IN ITALY

R. Bruni F. Bin

Istituto di Entomologia Agraria, Università degli Studi di Perugia

From 1974 to 1994, 82 phytophagous insect species, not previously recorded in the Italian fauna, have been scored. Most of them are nonindigenous pests against which some natural enemies have been introduced.

Six exotic entomophagous species have been used in planned programs while 13 have been found to exert some fortuitous control. Against 24 pests, including indigenous and long established exotic ones, 33 species of entomophages have been recorded. Of these, 22 were utilized using a classical approach and 11 had acted in a fortuitous way.

On average, over 20 years, host/entomophage fortuitous associations have occurred with a rate of 1.1 per year, while in planned programs the rate was 1.4. In a previous review (1974), reporting only the classical approach, a rate of about 0.7 was scored.

Efficacy was defined, when data were available, according to the usual parameters, i.e. complete, substantial and partial control. When establishment of an introduced species failed, a qualitative analysis of causes was attempted but definite results were not obtained because of lack of information and lack of follow-up studies. Therefore the adoption of rigorous protocol procedures to improve the success rate or explain failed introductions is recommended.

BIOLOGICAL CONTROL EXPLORATION AND RESEARCH BY THE OFFICE OF INTERNATIONAL RESEARCH PROGRAMS, AGRICULTURAL RESEARCH SERVICE, UNITED STATES DEPARTMENT OF AGRICULTURE

R. S. Soper¹, L. Knutson², H. Cordo³, C. E. Turner⁴, Q. G. Lu⁵.

1 Office of International Research Programs, Beltsville, MD USA - 2 European Biological Control Laboratory, Montpellier, France - 3 South American Biological Control Laboratory, Hurlingham, Argentina - 4 Australian Biological Control Laboratory, Brisbane, Australia - 5 Sino-American Biological Control Laboratory, Beijing, China. Permanent laboratories and staff are maintained in France, China, Argentina, and Australia as bases for exploration and research on natural enemies of major insect pests and weeds immigrant to the United States. In addition to exploration for new natural enemies, the 4 laboratories ship natural enemies to U.S. cooperators via quarantine labs in the U.S., study basic biologies, emphasizing host range testing and any other information needed for implementation of the biocontrol agents in the U.S. Cooperative linkages with host country and other national labs and researchers, including training of students, are emphasized. OIRP Headquarters also funds short-term explorations by U.S. researchers.

20-173

SCYMNUS COCCIVORA AIYAR (COLEOPTERA:COCCINELLIDAE) AN INDIGENOUS PREDATOR OF GRAPE MEALYBUG

T. RAMESH BABU AND D.D.R. REDDY

Department of Entomology, College of Agriculture

A.P. Agricultural University, Rajendranagar, Hyderabad, INDIA

Mealybug, *Maconellicoccus hirsutus* Green is the most devastating species in grape ecosystem. During surveys the coccinellid, *Scymnus coccivora* Aiyar was found feeding on eggs and crawlers of *M. hirsutus* in the field.

The effect of temperature on the developmental duration of *S. coccivora* was quantified by deriving a regression equation for each developmental stage as well as the total life cycle. Daily/overall consumption of prey by predator was established. Preference of the predator to *M. hirsutus* compared to other mealybugs was evident. Based on these biological aspects the mass culturing of *S. coccivora* was standardised.

Further, to conserve the naturally existing population several pesticides (five insecticides, one acaricide and three fungicides) were evaluated against *S. coccivora* adults to determine safe pesticides along with waiting periods by calculating the median lethal time (LT) values in days following probit analysis. Dichlorvos 0.1% and tridemorph 0.05% were found to be safest insecticide and fungicide, respectively and can be integrated with predator release. Synthetic pyrethroids and triadimefon (a systemic fungicide) were highly toxic and foils the additional advantage of utilisation of bio-agent.

20-174

OVIPOSITION STRATEGIES OF LADYBIRDS (COLEOPTERA: COCCINELLIDAE) IN THE SPRING ALFALFA FIELD

K. Takahashi, T. Maoka, T. Terauchi

Japan International Research Center for Agricultural Sciences, Okinawa Subtropical Station, Ishigaki, Okinawa, Japan

In the spring alfalfa field, the overwintered adults of *Coccinella septempunctata brucki* began their oviposition in the early spring when the aphid density was still low. *C. septempunctata brucki* laid their eggs mainly on undersides of dead leaves in the field. *Harmonia axyridis* began oviposition in the middle spring when the aphid density was rather high. *H. axyridis* preferred undersides of alive leaves of alfalfa for their oviposition sites.

In the laboratory condition, *H. axyridis* laid their eggs mainly on alfalfa. On the contrary, *C. septempunctata brucki* scarcely laid their eggs on alfalfa nor on the sites conditioned with their excretion.

The oviposition style of *C. septempunctata brucki* is seemed to escape the egg cannibalism by adults and larvae searching aphids on the alfalfa under the low aphid density. *H. axyridis* has less fear of egg cannibalism under the high aphid density and they lay their eggs on the alfalfa.

20-176

AUGMENTATIVE BIOLOGICAL CONTROL OF GRAPE MEALYBUG, *PSEUDOCOCCUS MARITIMUS* (EHRHORN) (HOMOPTERA: PSEUDOCOCCIDAE), IN PEAR

J.E. Dunley, R.H. Miller

Tree Fruit Research & Extension Center, Washington State University, Wenatchee, WA USA

Over the past several years the grape mealybug (GMB), *Pseudococcus maritimus* (Ehrhorn), has become an increasingly important pest of pear in the northwestern US. Reasons for the enhanced pest status include depletion of the natural enemy pool due to historically heavy pesticide use, increased resistance to organophosphate pesticides, and the cancellation of labels for pesticides previously used to control GMB.

The potential of two endemic biological control agents was examined using inclusion cages into which different densities of natural enemies were placed along with established populations of GMB. The experimental blocks were untreated with insecticides. The green lacewing, *Chrysoperla rufilabris* (Burmeister) significantly decreased GMB densities on infested pear branches. Another very common predator, the European earwig (*Forficula auricularia* L.) also significantly reduced GMB populations. Grape mealybug egg mass densities were significantly reduced by *C. rufilabris* or *F. auricularia* releases. Mass releases of lacewing eggs on GMB-infested trees resulted in decreased GMB numbers on the release trees and surrounding trees. There were few endemic predators or parasitoids present in GMB-infested pear blocks treated with insecticides or adjacent to pear or apple orchards under conventional spray programs.

20-175

THE FUNCTIONAL RESPONSES OF TWO *HYPERASPIS NOTATA* MULSANT (COLEOPTERA: COCCINELLIDAE) STRAINS TO THEIR PREY, THE CASSAVA MEALYBUG *PHENACOCCLUS MANIHOTI* MATILE-FERRERO (HOMOPTERA: PSEUDOCOCCIDAE)B. Stäubli Dreyer, J. Baumgärtner¹, P. Neuenschwander², S. Dorn³

Ittigen, Switzerland - 1 Agricultural Bureau of the Grisons, Chur, Switzerland - 2 International Institute of Tropical Agriculture, Plant Health Management Division, Cotonou, Republic of Benin - 3 Institute of Plant Sciences, Division of Phytomedicine, ETH Zentrum, Zürich, Switzerland

The number of prey individuals attacked by single larvae and adults of the coccinellid *Hyperaspis notata* Mulsant as affected by the density of its prey the cassava mealybug, *Phenacoccus manihoti* Matile-Ferrero, was studied in the laboratory. The parameters of a demand-driven functional response model for two strains of *H. notata*, one originating from Southern Brazil and one from Colombia, were compared. In the case of larvae there were no differences between the Brazilian and the Colombian strain. Adult females of the Colombian strain, however, showed a greater searching rate but a lower prey demand rate than females of the Brazilian strain.

20-177

THE BIOLOGY OF THE MEALYBUG, *NIPAECCUS VIRIDIS* (NEWSTEAD), (HOMO.: PSEUDOCOCCIDAE) AND EVALUATION OF THREE LADYBIRDS SPECIES (COL.: COCCINELLIDAE) IN ITS BIOLOGICAL CONTROL IN SOUTHWEST, IRAN. Mossadegh, M.S. & A. Khodaman

Department of entomology, College of Agriculture, Shahid Chamran University, Ahwaz, Iran.

The mealybug, *Nipaeccus viridis* (Newstead) is one of the major pests of citrus spp. in Khuzestan province, southwest, Iran. In a two years survey (1991-93), the biology of the mealybug, was studied in the field and laboratory conditions. The biological aspects of *N. viridis* were studied on sprouted potato tubers at 20±1.30°C. and 26±1.30°C., 70±5%RH and under photoperiod LD 12:12. This mealybug completes 8 generations in a year, 7 during march-December and 1 during December-March at Ahwaz, conditions. Overlapping of successive generations took place and it over winters as egg, nymph and adult. It had two populations peaks in spring and autumn. The exotic predator *Cryptolaemus montrouzieri* Mul. and two other indigenous coccinellids *Hyperaspis polita* Weise and *Scymnus includens* Kirsch evaluated in biological control against *N. viridis* in the natural conditions. A number of young citrus spp. trees were infested with the mealybug crawlers in April 1992. To eliminate other biological agents, they were covered with white fabrics which were fixed on metal frames. Releasing of the coccinellids accomplished twice in April 1993. all the infested and control trees were sampled randomly in the end of December 1993. Analysis of data revealed the potential and capability of the three species of ladybirds in suppressing the mealybug population. However, *H. polita*, effectively acted better than other two species.

20-178

EFFECTS OF EXPERIENCE REGARDING PREY AND PLANT STRUCTURE ON PREDATION EFFICACY OF *COLEOMEGILLA MACULATA* LENGI TIMBERLAKE (COLEOPTERA: COCCINELLIDAE) ON *LEPTINOTARSA DECEMLINEATA* (SAY) (COLEOPTERA: CHRYSOMELIDAE)

S. Giroux, D. Coderre & R.-M. Duchesne¹

Département des Sciences Biologiques, Université du Québec à Montréal, Montréal (Québec) Canada. - ¹ Service de Phytotechnie, Ministère de l'Agriculture, des Pêches et de l'Alimentation du Québec, Ste-Foy (Québec) Canada.

Predation efficacy of *Coleomegilla maculata* fourth instars on *Leptinotarsa decemlineata* young instars was investigated to look at the effects of experience in regard of the prey and the plant structure. Rearing conditions (artificial diet vs *L. decemlineata*; plant structure vs plastic container) did not affect the number of prey attacked over a 24h period. However in the first 3h, predators reared on artificial diet attacked significantly more prey than predators reared on *L. decemlineata*. This difference was not observed between naive predators and *L. decemlineata*-reared ones that had been put on artificial diet for 72h. Further investigations showed (1) that level of experience regarding the plant structure affected space and time partitioning of searching behavior, and (2) that prey-experimented predators needed more contacts with prey in order to attack, and rarely consumed the prey totally. Development of a food aversion towards *L. decemlineata* is likely to explain these results.

20-180

CRITICAL ISSUES IN REARING APHIDOPHAGOUS COCCINELLIDAE

I. Hodek

Institute of Entomology, Academy of Sciences,
Č.Budějovice, Czech Republic

While in the field crops fostering native populations of aphidophagous ladybeetles is preferred, inundative releases are necessary for biocontrol in glasshouses; mass cultures are then a prerequisite. Three phenomena are critical in artificial rearing: (1) diapause, (2) prey specificity and (3) cannibalism.

(1) Continuous rearing can be achieved by the use of photoperiods preventing diapause, i.e. long daylength or increase in daylength in most species from cold temperate Europe, but short daylength in, e.g., *Coccinella septempunctata brucki* in central Honshu, Japan. In the species with strong tendency to univoltinism, this tendency can be gradually eliminated by selection, or multivoltine populations from other climatic region may be used when founding the culture. However, diapause can be used to our advantage for easier storage of viable adults; they can be produced by an appropriate sequence of feeding on aphids and alternative foods, based on honey or pollen.

(2) Successful rearing (high fecundity, high survival during larval development) on non-aphid food (eggs of Lepidoptera or Coleoptera, lyophilized larvae of honey bee males, plant pollen) can be achieved only in polyphagous species (e.g. *Coleomegilla maculata*, *Harmonia axyridis*). For oligophagous species (e.g. *Coccinella* spp.) certain aphids are less suitable or even toxic, usually due to allelochemicals from the host-plants of their aphid prey.

(3) Cannibalism can be limited by steady presence of surplus of prey, and providing much "walking" surface in the rearing cages.

(For more details see Hodek I. & Honek A., Ecology of Coccinellidae, 1996, Kluwer.)

20-179

RECORDS OF COCCINELLIDAE (COLEOPTERA) SPECIES PREYING ON COCONUT PESTS IN THE STATE OF ALAGOAS, NORTHEASTERN REGION OF BRAZIL: *OLLA V-NIGRUM* (MULSANT, 1866) AND *CYCLONEDA SANGUINEA SANGUINEA* (L., 1763) ON *CERATAPHIS* SP (HOMOPTERA, APHIDIDAE) AND *CHILOCORUS NIGRITA* (FABRICIUS, 1798) ON *ASPIDIOTUS DESTRUCTOR* (SIGNOTRET, 1869) (HOMOPTERA, DIASPIDIDAE)

I. M. de M. Lima

Departamento de Zoologia - Centro de Ciências Biológicas / Museu de História Natural da Universidade Federal de Alagoas, Universidade Federal de Alagoas, Maceió, Alagoas, Brazil

O. v-nigrum (Coccinellinae, Coccinellini) is well known as an aphid and psyllid predator. This is the first time that it was found preying on *Cerataphis* sp (Homaphidinae, Cerataphidini). All the life stages were collected in the field. Among the adults two color patterns were found for the species: the melanic form (more common) and the pale form. In *C. sanguinea sanguinea* (Coccinellini), primarily an aphid predator, all the life stages were detected in the field but in a lower density than in *O. v-nigrum*. *C. nigrata* (Chilocorinae, Chilocorini) an oriental Coccinellidae used as an introduced biocontrol agent of Diaspididae species in many regions of the world, was found preying on *A. destructor* a serious pest on young coconut palms. Its abundance and its presence on scale colonies on various plant species, could be an indicator of the establishment of this species. The improvement of its efficiency in the field could be reached by releasing adults from mass rearings. For *C. nigrata* simple techniques could be applied by using *Diaspis echinocacti* (Bouché, 1833) (Diaspidinae, Aspidiotini) growing on Cactaceae species - *Nopalea cochenillifera* (L.) Salm.-Dick and *Opuntia ficus-indica* (L.) Mill - as a food resource for the Coccinellidae. As *O. v-nigrum* and *C. sanguinea sanguinea* preying *Cerataphis* sp is a record, it is necessary to study possibilities of its rearing in laboratory conditions to be released in crop fields with infestation problems.

20-181

EFFICIENCY OF *Hippodamia convergens* GUERIN-MENEVILLE AS A PREDATOR OF *Thrips tabaci* LINDEMANN

M. Schade and Ç. Şengonca

Institute of Phytopathology, University of Bonn, FRG

In order to develop specific biological control methods, suitable for target pest, sufficient knowledge about the biology and ecology of the beneficial insect is very important. Hence laboratory studies were conducted on the development, feeding activity and prey preference of *Hippodamia convergens* Guerin-Meneville (Col., Coccinellidae) as a potential predator of *Thrips tabaci* Lindeman (Thys., Thripidae). Since this predator is primarily provided for field releases against thrips on leek, experiments were carried out in specially prepared bioassay chambers designed for the prey to prevent possible predation. All experiments were conducted at 16 h of artificial illumination at a temperature of 24±1 °C and 8 h of darkness at 18±1 °C. In the control chambers *H. convergens* was exclusively fed aphids.

H. convergens developed fully on *T. tabaci*. Larval mortality was considerably higher than in the control. It reached an average of 48 % in the first two larval instars, whereas there was only 10 % mortality in the control. Development was clearly delayed taking 32.0 days on thrips, but only 23.8 days on aphids. Furthermore, constant feeding on thrips resulted in considerably smaller adults. The females laid pale-yellowish eggs, which developed normally. Feeding activity increased continuously during development and reached more than 200 thrips per day for L₄-larvae and more than 300 for the adults. There was a slight increase in the preference for the predation of aphids when compared to the predation of thrips.

20-182

SEASONAL DISTRIBUTION OF COCCINELLIDAE PREYING APHIDS IN AN INTENSIVELY CULTIVATED AGROECOSYSTEM (COLEOPTERA - RHYNCHOTA: APHIDOIDEA)

G. Nicoli, R. Ferrari¹, G. Burgio

Istituto di Entomologia 'G. Grandi', Università di Bologna, Italy - 1 Centro Agricoltura e Ambiente, Crevalcore (BO), Italy

The seasonal movements of Coccinellidae were investigated in the simplified biotic communities of a plain agroecosystem in northern Italy, with the aim of improving the natural control of aphids. For five years, collections by frapping and visual samples were systematically used to identify the preferred sites of overwintering and reproduction. Although fluctuations were recorded, three general trends were observed. 1) In springtime, adults regularly move from winter shelters to infested plants where they feed and reproduce. Wheat is the principal extensive crop colonised by *Adonia variegata* (Goeze), *Propylaea 14-punctata* (L.), and *Coccinella 7-punctata* L.; peach trees are often preferred by *Adalia 2-punctata* (L.) and some Scymnini; white poplar and blackthorn by *A.2-punctata*, Scymnini, *A.variegata*, and *Synharmonia conglobata* (L.); stinging nettles by *A.variegata*, Scymnini, *A.2-punctata*, and *C.7-punctata*. 2) In June and July, newly-emerged adults colonise the summer crops and start the second generation. Corn, sugar beat, sorghum, melon, watermelon, and other vegetables are preferred by *A.variegata*, *P.14-punctata*, *C.7-punctata*, and Scymnini; pear, apple, and peach trees mainly by *P.14-punctata*, *A.2-punctata*, and Scymnini. 3) At the end of summer, when extensive crops are harvested and many other plants dry out, adults leave the inhospitable canopies and move to hedges, grass-lands, and orchards, preparing for overwintering. Alfa-alfa appears to be the unique crop supporting large amounts of Coccinellidae during the year because it is regularly re-colonised after each cutting. In general, the polyvoltine species play a primary role in the natural control of aphids and the possibility of forecasting the colonisation times enhances the Integrated Pest Management in several crops. Biodiversity is essential for the permanence of predators in the agroecosystem, although wild plants are rarely significant reproduction sites, due to the limited surface and the generally low aphid infestations.

20-184

REARING METHOD FOR PREDATORY FLIES OF THE GENUS *COENOSIA* (MG.) (DIPTERA: MUSCIDAE) - NEW BENEFICIALS OF BIOLOGICAL CONTROL

St. Kühne, R. Müller

Federal Biological Research Centre for Agriculture and Forestry, Institute for Integrated Plant Protection, Kleinmachnow, Germany

The development of a rearing method for the predatory flies *Coenosia atra*, *C. attenuata*, *C. humilis* and *C. strigipes* will provide a new group of beneficials to biological pest management in glasshouses.

Their prey range comprises for instance white flies, (Aleurodidae), sciarid flies (Sciaridae) and leaf-miners (Agromycidae). The predatory

Coenosia larvae feed on larvae of sciarid flies (Sciaridae: *Bradysia paupera* Tuomikoski) for which we have developed a specific rearing method. In contrast to all known methods larvae feed on a nutrient fungus which is cultivated in a wood-fibre-bark substrate.

Investigations have shown that sciarid flies lay their eggs on fungal mycelium and that the larvae prefer fungal hyphae of the genera *Fusarium*, *Botrytis* and *Alternaria*. *Coenosia* females lay their eggs on the surface of this rearing substrate. The predatory larvae of *C. strigipes* hatch after 5 days at 25°C and pupate after approx. 11 days.

After another 11 days imagines hatch. Commercial production of the flies will start in Germany in 1996.

20-183

FEEDING PREFERENCE, BETWEEN APHID AND COLLEMBOLAN PREY, OF AN ABUNDANT CARABID BEETLE, *PTEROSTICHUS CUPREUS*, ASSOCIATED WITH CEREAL FIELDS.

C. Mundy, L. Allen-Williams, N. Underwood

Department of Environmental Sciences, University of Hertfordshire, Hatfield, Herts, AL10 9AB.

In five different treatments the feeding preferences of *Pterostichus cupreus* adults (L), (Coleoptera, Carabidae) for the cereal aphid, *Metopolophium dirhodum*, (Walk.), or the Entomobryid collembolan *Heteromurus nitidus* (Templeton), was examined. *P. cupreus* exhibited higher consumption rates of aphids than of collembolans when offered both prey types simultaneously. Conversely, the consumption rate of collembolans was higher than of aphids when prey types were offered separately. Total consumption rates were not significantly lower when *P. cupreus* was offered both prey items simultaneously. In all treatments in which both prey items were presented simultaneously, the percentage of grid squares where *P. cupreus* consumed aphids first, was always significantly greater ($P < 0.05$). Beetles given a 5 day pre-experimental diet of aphids only, did not have a significantly different consumption rate of either prey type nor was there a significant change in percentage of squares where aphids were consumed first. Beetles given a 5 day pre-experimental diet of collembolans only, had a significantly lower consumption rate of aphids, ($P < 0.05$) and a lower percentage of grid squares where an aphid was consumed first ($P < 0.05$). It was concluded that aphids were consumed in preference to collembolans under the experimental conditions, and that prey selection can be affected by the diet previous to prey selection.

20-185

GREEN LACEWINGS (NEUROPTERA: CHRYSOPIDAE) IN DALMATIAN OLIVE ORCHARDS

K. Žanić¹, J. Igrc Barčić², S. Kačić¹¹ Institute for Adriatic Crops, Put Duilova 11, Split, Croatia - ² Department of Agricultural Zoology, Agricultural faculty, Svetošimunska 25, Zagreb, Croatia

Neuroptera of Croatia, especially Neuroptera of Dalmatia, are only a few insufficiently investigated. Particularly, there are data about distribution and beneficial activity of Neuroptera from the agricultural point of view

In order to collect the first detailed information on the Neuroptera Chrysopidae, present in Dalmatian olive orchards, four experimental sites (Podgora, Duilovo, Kaštel Stari and islands Sit and Žut - Komati archipelago) were selected to be investigated during the vegetation periods in the years 1990 and 1991. In these orchards, chemical treatments were not applied and olive trees were attacked by *Prays oleae* Bem. and *Saissetia oleae* Oliv. Therefore those sites were rich with fauna from family Chrysopidae.

Our aim was to establish the list of our autochthonous Chrysopid species and investigate some morphological and biological characteristics.

Standardized and auxiliary collection methods of adults were used (Klopimethode - Steiner 1962, Mc Phail Traps for monitoring of *Dacus oleae* Gmel., Fluorescent Yellow Traps and Catching Lamp). We observed that Mc Phail traps, filled with hydrolysate protein or $(\text{NH}_4)_2\text{HPO}_4$, caught Chrysopid species which were not predaceous in the adult stage.

At the experimental site of Podgora six species were found, while in other sites seven species were identified. The most frequently species found was *Chrysoperla carnea* Steph. which was the only one that had been present throughout the year in Dalmatia. The less frequent species were *Mallada zelleri* Sch. and *Chrysopa pallens* Ramb.

The dynamics of flight and the share of various species were additionally investigated in orchards Duilovo and Kaštel Stari and will be presented.

20-186

THE ROLE OF SPIDERS AS NATURAL CONTROL AGENTS IN A COTTON AGROECOSYSTEM FROM ARGENTINA

Cristina Luisa SCIOSCIA

Laboratorio de Aracnología. Museo Argentino de Ciencias Naturales. Av. A. Gallardo 470 (1405) Buenos Aires. Argentina

The relevance of spiders as natural enemies of insect pests have been evaluated during two years, in the framework of an Integrated Pest Management Program of Cotton Insects developing at the Experimental Agronomic Station of Presidencia Roque Sáenz Peña (Chaco, Argentina).

The records of biodiversity, abundance and distribution of spiders in sprayed and unsprayed fields were compared. Thomisidae, Araneidae, Philodromidae and Lycosidae were the dominant spider families in the crop. The present results clearly demonstrate that spraying of insecticides caused a serious drawback in spider populations.

Laboratory bioassays were carried out to observe spiders prey preferences for three Lepidoptera larval instars (*Alabama argillacea*, *Heliothis virescens* and *Spodoptera frugiperda*) and for a cotton bug, *Dysdercus chaquensis* (Heteroptera). The standard reference preys were *Musca domestica* or *Drosophila melanogaster* (Diptera). These assays showed that spiders preferred Lepidoptera larvae. Only Araneids fed upon *Dysdercus chaquensis*.

Consumption rates of *Heliothis virescens* larvae by *Misumenops pallens* (Thomisidae) were also determined. Males and females of *Misumenops pallens* consumed daily mean rations of 0.95 mg and 6.15 mg of *Heliothis virescens*, respectively.

20-188

COMPARATIVE CONSUMPTION LEVEL OF *CHRYSOPERLA EXTERNA* (HAGEN) AND *CERAEOCHRYSA PARAGUARUA* (NAVAS) (NEUROPTERA: CHRYSOPIDAE) FEEDING *HELIOTHIS VIRESCENS* (F.) (LEPIDOPTERA: NOCTUIDAE) EGGSM. Polak¹, A. Ruiz¹, G. Contreras¹, G. Videla¹, E. González Olazo²¹ Departamento de Entomología, Instituto Nacional de Tecnología Agropecuaria, Sáenz Peña, Chaco, Argentina² Fundación Miguel Lillo, Tucumán, Argentina

Samplings performed in the Domo Central Agrícola Chaqueño area of Argentina, using nets and light traps from 1992 to 1995, showed that *Chrysoperla externa* (Hagen 1856) and *Ceraeochrysa paraguaria* (Navás 1924) are the most abundant Chrysopidae present in cotton crops.

The objective of the present study was to comparatively measure the consumption of *Heliothis virescens* eggs performed by both species.

Tests were conducted under controlled conditions (25±3°C; 75±10% RH; 14:10 L:D). Experimental units were represented by plastic containers with three compartments of 2x2x1 cm each. Eggs of either species were individually placed in each compartment. Hatched larvae were fed *H. virescens* eggs *ad-libitum*. Consumption was registered by day and by stadium.

Each *C. paraguaria* larva consumed a total average of 628.9 (±44.9) eggs of the prey during the 13.5 (±0.7) days the larval stage lasted in average. *C. externa* larvae individually consumed a total average of 519.5 (±63.5) prey eggs during the 10.8 (±1.7) days the larval stage lasted in average. Both species significantly differed with respect to total consumption and duration of larval stage. Significant differences in consumption were also found among stadia within species and between each stadium of both species.

20-187

A NEW METHOD TO QUANTIFY THE PREDATION BY POLYPHAGOUS PREDATORS IN THE FIELD BY MARKING THEIR PREY WITH THE STABLE ISOTOPE ¹⁵N

K.M. Nienstedt, H.M. Poehling

Institut für Pflanzenkrankheiten und Pflanzenschutz, Universität Hannover, Herrenhäuser Str. 2, 30419 Hannover, Germany

In various publications polyphagous predators are described to have an influence on the population level of agricultural pests like aphids, but the quantification of this impact in the field is difficult. Until now methods like electrophoresis, ELISA and enclosure-experiments have been used, yet all of them entail some problems with the interpretation of the data.

An alternative approach is marking the prey and following up the marker in the predators. Commonly used markers are radioactive isotopes and rare elements, but they can influence the behaviour of the prey. Furthermore radioactivity can cause contamination of the environment. The use of stable isotopes for the marking can help to avoid these problems: they are safe because they do not cause contamination and they do not alter the behaviour of the marked animals.

We propose a new method in a model system which consists in marking cereal aphids of the species *Sitobion avenae* (Homoptera: Aphididae) by increasing their natural level of ¹⁵N by feeding, and detecting later increased levels of ¹⁵N in polyphagous predators that ingested marked aphids by mass spectrometry. As predators we used *Platynus dorsalis* (Coleoptera: Carabidae) and *Erigone atra* (Araneae: Linyphiidae). The level of the tracer detected in these predators did not decline for at least 10 days after a marked prey was ingested, an important difference to other methods like ELISA where the prey can be detected only for shorter periods. First results of these and additional experiments are presented and the suitability of this method for the quantification of predation in the field is discussed.

20-189

'FORFICULA DECIPIENS' GENE', A NEW MULTIPREY PREDATOR FOR BIOLOGICAL CONTROL: BIOLOGICAL AND ETHOLOGICAL ASPECTS

G. Vita, P. Bonavita¹, M.R. Tabilio²

Enea-Dipartimento Innovazione, Roma, Italy - 1 Centro di Ecologia Alpina della Provincia di Trento, Italy - 2 MIRAF-Istituto di Frutticoltura, Roma, Italy.

Forficula decipiens Genè is a species of Dermaptera diffused in the Mediterranean area. The trophic habit of the young larvae is prevalently insectivorous but pollen and fungal spores may be feeded. Contrary to *Forficula auricularia* L., closely related species *F. decipiens* never has been recognized as a dangerous pest of cultivated plant. In this work is demonstrated that the sub-social behaviour of the *F. decipiens* larvae gives the opportunity to employ the predator in familiar groups located in wooden nests attached at the bottom of the trunk. Preliminary trials demonstrate the ability of the earwigs (second and third larval stage) to prey aphids (young and adult stage), lepidoptera eggs, red spidermites, larvae of tripids and whitefly larvae.

In laboratory, a large colony of *F. decipiens* was reared in order to obtain a mass production of the predator. In the field it was checked the ability of this earwig to control: aphids infestation on peach plant (3 years of observations); *Lobesia botrana* Schiffmüller attacks on vineyards (3 years of observations); red spidermite infestation on the strawberry (1 year of observations). CONCLUSIONS: The study carried out candidates the earwig *Forficula decipiens* to be a new multiprey predator of many important pest.

CLASSICAL BIOLOGICAL CONTROL OF CASSAVA GREEN MITE *MONONYCHELLUS TANAJOA* (BONDAR) IN AFRICA AND SOUTH AMERICA BY PHYTOSEIID MITES (ACARI: TETRANYCHIDAE, PHYTOSEIIDAE)

L. Smith, J. S. Yaninek¹, G. J. de Moraes², A. C. S. Noronha³

International Center for Tropical Agriculture, Cali, Colombia - 1
International Institute of Tropical Agriculture, Cotonou, Benin - 2
Centro Nacional de Pesquisa de Monitoramento e Avaliação de Impacto Ambiental, EMBRAPA, Jaguariúna, São Paulo, Brazil - 3
Centro Nacional de Pesquisa de Mandioca e Fruticultura Tropical, EMBRAPA, Cruz das Almas, Bahia, Brazil

The cassava green mite feeds on leaves and growing tips of cassava *Manihot esculenta* Crantz, an important tropical root crop. The mite is native to the neotropics but became established in Africa in the early 1970s, where it causes extensive damage. It is also a serious pest in the dry region of northeast Brazil, where there are few species of predators.

CIAT, EMBRAPA and IITA have been collaborating to find suitable natural enemies in South America to release in Africa and northeast Brazil. This involves matching the climate of target regions to identify regions to explore and evaluating candidate predators in the laboratory for prey specificity, adaptation to dry climate, and efficacy. Ecological data collected during explorations is also used to describe the predators' ecological niches. Over 25 new species of predaceous phytoseiids have been described, and taxonomic keys are being developed.

Three species of phytoseiids have been established in Africa. Of these, *Typhlodromalus aripo* de León *sensu lato* and *T. manihoti* (Moraes) are spreading rapidly and are reducing cassava green mite populations significantly. Two species released in northeast Brazil have been recovered in small numbers.

VEGETATION AND CARABID FAUNA AFFECTED BY CONVENTIONAL AND BIOLOGICAL CULTIVATION

A. Vasarainen and S. Kurppa

Agricultural Research Centre, Institute of Plant Protection, FIN-31600 Jokioinen, Finland

In southwestern Finland, 6755:311 (Uniform Grid System, 27E), the cover of cultivated and noncultivated plants was measured in a conventional and biological crop rotation experiment in 1992-1995. The Carabid beetles were sampled during the season using pitfall traps in 1991-1995.

The crops grown were winter rye, pea and oats as mixed crop, barley as a cover crop for first year gramineous hay, first year grass and second year grass. The size of every plot was about 0.6 hectare. Conventionally cultivated plots were fertilized by inorganic fertilizers and sprayed with herbicide. The biologically cultivated plots were organically fertilized and not sprayed at all.

The total cover and the cover of cultivated plants was higher in the conventionally cultivated areas.

The weed cover and the number of weed species was higher in the biologically cultivated areas. Altogether in the plots there were the cultivated plants and 47 weeds.

The total Carabid catch was 26 species and 9682 specimens. 54 % of the specimens were collected from biologically cultivated. The most abundant species during 1991-1995, representing 67 % of the whole catch, were *Pterostichus cupreus* L., *Pterostichus melanarius* Ill., *Bembidion guttula* F., *Bembidion gilvipes* Sturm and *Amara* sp. The composition of species did not differ between cultivation strategies. *Bembidion*-species were dominant in summer 1991 and *Pterostichus*-species in summer 1993 and 1995.

SPIDER POPULATIONS IN A TYPICAL FIELD SITE IN CENTRAL GERMANY AND SPECIAL INFLUENCES OF VARIOUS PLANT PROTECTION INTENSITIES DURING A CROP ROTATION SEQUENCE (1991 - 1995)

Ch. Volkmar

Martin-Luther-University Halle-Wittenberg, Agricultural Faculty, Institute of Plant Breeding and Plant Protection, 06099 Halle/Saale, Germany

From 1991 to 1995 field investigations were carried out on a site (Obhausen, Querfurt county) in the central German dry region. This agricultural area stands out for its highly productive black earth soils (loess over loam) with relatively poor annual precipitation as the limiting factor. The crop rotation sequence winter barley (break in spring 1992 because of drought), maize, winter wheat, winter wheat, winter rye was studied on a 43 ha field. For this purpose 6 plots sized 72 x 200 m each were established. On two control plots no plant protection measures were applied. Another two were intensively treated with herbicides, fungicides and insecticides. On the remaining two plots targeted control measures were carried out with regard to threshold values. The epigeous spiders were sampled by using 9 pitfall traps per plot.

Altogether (1991 to 1995) the 68 805 spiders belonged to 104 species of 17 families. In maize herbicidal treatments in May and June did not directly influence the activity density of the spiders. In winter wheat the control variants revealed the highest activities (average 4,5 spiders per day and trap). There was no statistical difference to the integrated pest management variant (\bar{x} 4,1 spiders per day and trap). Especially the field species *Oedothorax apicatus*, *Erigone atra*, *Erigone dentipalpis*, *Meioneta rurestris*, *Porrhomma microphthalmum*, *Pardosa agrestis* and *Pardosa pratvaga* which are well adapted to open habitats reached high dominance levels on the control plots and on specifically treated field sections. Their long retention time in the field, the early presence in spring and their predatory performance makes spiders interesting objects in the development of beneficial thresholds. Summarizing we can conclude that purposeful use of plant protection agents with consideration of damage thresholds tend to leave a major number of spiders in their natural habitat.

20-193

BIOLOGICAL CONTROL AGENTS OF MUSK THISTLE, *CARDUUS NUTANS* (COMPLEX) IN THE UNITED STATES.

P. E. BOLDT,¹ G. CAMPOBASSO,² G. TERRAGITTI²

USDA/ARS GRASSLAND, AND WATER LABORATORY, TEMPLE, TEXAS-1
USDA/ARS EUROPEAN BIOLOGICAL CONTROL LABORATORY, ROME, ITALY - 2

Classical biological control of weeds uses introduced insects or pathogens to reduce the abundance of a weed to below its economic threshold. Musk thistle, *Carduus nutans* L., complex (Asteraceae), is a spiny, noxious herbaceous plant that chokes pastures, rangelands, and roadside areas. In the United States this weed is successfully controlled in many middle Atlantic and Midwestern states by the release of host specific insects. These insects are collected in Europe by personnel of the USDA/ARS Biological Control Laboratory - Europe. Two weevils, *Rhinocyllus conicus* (Froelich) and *Trichosiromus horridus* (Panzer), are responsible for most of the reduction in musk thistle density. Two flies, the syrphid, *Cheilosia corydon* (Fallén), and the tephrid, *Urophora solstitialis* (L.) are recent introductions for use against musk thistle in other areas of the country but are not yet well established. A strain of the rust fungus, *Puccinia carduorum* Jacky, also was tested and is ready for distribution in the Plains area.

BIOECOLOGICAL ASPECTS OF *LAMPROSOMA AZUREA* GERMAR, 1824 (CHRYSEMELIDAE, LAMPROSOMATINAE) FEEDING ON *PSIDIUM CATTLEIANUM*, SABINE, 1821 (MYRTACEAE)

M.G.Caxambú, L.M.Almeida¹

Departamento de Zoologia, Universidade Federal do Paraná, Curitiba, Paraná, Brazil

In 1991 an agreement between "Universidade Federal do Paraná" and Hawaii University, Manoa, Hawaii, was established in order to recognize the potencial associates insects for the biological control on *Psidium cattleianum* Sabine, 1821 (Myrtaceae).

Lamprosoma azurea Germar, 1824 has been found on this plant in Curitiba, Parana State, Brazil, feeding on the apical parts, causing serious damage. The egg, larvae and adult are described and illustrated. Some biological aspects of this species are provided.

20-196

GENETIC DIVERSITY IN LIFE HISTORY TRAITS BETWEEN POPULATIONS OF THE *DROSOPHILA* PARASITOID, *LEPTOPILINA HETEROTOMA* (HYMENOPTERA: EUCOILIDAE).

F. Fleury, R. Allemand, C. Lemaître, P. Fouillet and M. Boulétreau
Laboratoire de Biométrie, Génétique et Biologie des Populations,
URA CNRS 2055- Université Claude Bernard-Lyon I. France.

Parasitoid insects are exposed to particular selective constraints because the larval stages live as parasites whereas adults live freely. Thus, a close adaptation is expected in response to variations of their environment.

The species *Leptopilina heterotoma*, a parasitoid of *Drosophila* larvae, is widespread in Europe and shows important variations in life history characters according to geographic origin. Parasitoids originating from mediterranean area show a high rate of locomotor activity, a bimodal circadian rhythm and a high parasitization efficiency. On the other hand, parasitoids collected more in the north have an unimodal rhythm with a low rate of activity and a parasitization efficiency twice less important. Crosses between strains have demonstrated the genetic basis of these variations thus suggesting a local adaptation to selective pressures of the environment.

The geographic differences among populations of *L. heterotoma* could be correlated with climatic latitudinal variations. Furthermore they are also correlated with the presence of *L. boulandi*, the main competitor of *L. heterotoma* in the mediterranean area. The selective role of this interspecific competition is strongly suggested by the clear shift in the phase of circadian activity rhythms of both species which results in a temporal sharing of hosts.

Current studies are trying to evaluate the contribution of the different selective constraints emanating from abiotic environment and from the whole complex of *Drosophila* associated parasitoids.

20-195

CHARACTERIZATION OF A TERATOCYTE-SPECIFIC 540 KDA PROTEIN IN THE BRACONID WASP, *PERILITUS COCCINELLAE* SCHRANK (HYMENOPTERA: BRACONIDAE)

T. Okuda, K. Kadono-Okuda

Department of Insect Physiology and Behavior,
National Institute of Sericultural and
Entomological Science, Tsukuba, Ibaraki, Japan

Perilitus teratocytes became hypertrophic to such an extent that some teratocytes attained a maximum diameter of 820 µm. The number of teratocytes, however, decreased gradually and few or no teratocytes remained in the host body cavity after the parasitoid larva egressed. Changes of the total protein content of teratocytes and parasitoid larvae indicated that the teratocytes may have a role in providing nutrients for the developing parasitoid larvae. This hypothesis was supported by the fact that the gut content of the parasitoid larvae showed an immunoreaction to antibodies against crude teratocyte proteins. We further characterized the 540 kDa teratocyte-specific protein and discussed the function of the *Perilitus* teratocytes.

20-197

MICROSATELLITE AND GENETIC DIVERSITY IN THE ASEXUAL PARASITOID, *VENTURIA CANESCENS*.

W. Whitfield, S. Hubbard & R. Butcher.

Department of Biological Sciences, Dundee University, Scotland.

Venturia canescens is an obligate parthenogenetic solitary endoparasitoid of phytophagous moth larvae. The parthenogenesis is not induced by *Wolbachia* or microsporidians and is not cured by antibiotics or heat treatment. No detectable genetic diversity could be detected by alloenzyme studies within or between isolates or clones, but the mechanism of diploid restoration is not certain.

We have cloned, sequenced and characterised over 670 microsatellites from *Venturia canescens*. The genome displays a strong bias to dinucleotide repeats with very few tri- or tetra-nucleotide repeat motifs. Additionally, almost all the microsatellites are small (n<10) and most contain inserts and thus are stable, with no detected polymorphism between isolates.

However, utilising PCR primers to the loci-specific microsatellites we have probed for the genetic diversity between different geographical isolates, between established clones within an isolate, and within the progeny of a single clone of *Venturia canescens*. The data are presented and applications to the behavioural, sexual and evolutionary biology of *Venturia canescens* are discussed and illustrated.

20-198

AN EXPERIMENTAL AND THEORETICAL MODEL TO EXPLAIN SEX-DETERMINATION IN THE ENDOPARASITOID *DIADROMUS PULCHELLUS* (ICHNEUMONIDAE) : VALIDATION OF THE ONE-LOCUS MODEL.

R. Kalmes¹, M. Gillois², D. Rousse¹

¹ Institut de Recherche sur la biologie de l'insecte (URA CNRS 1298), Université de Tours, France. ² INRA, Département de génétique cellulaire, Toulouse, France.

The competition of endoparasitoid larvae associated with superparasitism has different consequences whether the wasps are gregarious or solitary. However in both case, the ratio of haploid versus diploid wasps produced is modified and the adaptative value of the population is increased.

We have studied the proportion of the eggs giving rise to adults in the solitary wasp *Diadromus pulchellus* (Ichneumonidae). First, taking into account the production of both haploid and diploid males by the females, we have measured the viability of eggs, larvae and pupae without larval competition with the "egg selection coefficient" and the "larval-nymphal selection coefficient".

The study of this coefficient in our experimental population shows four distinct groups of females according to the sex-ratio of their offsprings. These experimental groups are those expected by the theoretical transmission of sexual alleles under the one locus model.

The results show that the probability to develop into an adult that in the laboratory population is higher for a female egg (diploid) than for a male (haploid or diploid).

Lesser Wax moth, *Achroia grisella* Fab. and its Parasitic Wasps.

H.Goldansaz, M.Esmaili, and R. Ebadi

1- Dep.Plant prot. Colleg of Agri. Tehran Univ. Karaj, IRAN.

2- Dep.Plant prot. Colleg of Agri. Isphahan Univ. of Technology, IRAN.

Lesser Wax moth, *Achroia grisella* is one of the important Pests of honeybee, destroying wax combs mainly in the storage. life cycle when reared on old wax comb under 29-31 temp. and 65-75% R.H. decreased the duration of larval period.

In an investigation for number of larval instars, it has been found.

Two species of Parasitoides have been Collected. They are *Dibrachys boarmiae* and *Apanteles galleriae*. This is the first report on this insects in IRAN.

20-199

PARASITISM BY *METEORUS RUBENS* ON *AGROTIS IPSILON* AS AFFECTED BY SUPPLEMENTARY FOOD AND KAIROMONE, FIELD STUDIES.

Fayez, M. Zaki¹, K.T. Awadallah², and M.A. Gesraha¹.

1. Pests and Plant Protection Dept., National Research Centre, Dokki, Cairo, Egypt.
2. Biological Control Lab., Fac. Agriculture, Cairo Univ., Giza.

Field experiments in clover field showed that releasing of 10 mated *M. rubens* females/m², increased parasitism among *A. epsilon* larvae from 16.7% at 0-day to 43.3% after 10 days. Also, releasing 10 females/m² after spraying 3% molasses in tomato field increased parasitism from 4% at 0-day to 27.5% after 10 days among *A. epsilon* larvae. Spraying molasses and kairomone together on maize plants, increased markedly the rate of parasitism among *S. cretica* larvae comparing with parasitism obtained when each of them was sprayed alone. The release of *M. rubens* in a rate of 10 females/m² after spraying molasses and kairomone induced a significant increase in the rate of parasitism among *S. cretica* larvae after 10 and 15 days compared to releasing 3 or 4 females of the parasitoid.

A significant increase in parasitism among *S. cretica* larvae on tomato after 10 and 15 days was recorded when *M. rubens* was released at the rates of 5 and 10 females/m² after spraying molasses and kairomone, compared to other treatments.

20-201

Some Hymenopterous parasitoids and their potentialities on controlling alfalfa aphids in Karaj, Iran.
Dr. Gh. Reza. Rassoulan.

Two alfalfa aphid species, *Acyrtosiphon pisum* (harris) and *Therioaphis trifolij* forma maculata (Buckton) are the economic importance pests on alfalfa in Iran.

In order to investigate the identification and the effect of some hymenopterous parasitoids, sampling of aphids has been done weekly during the spring and summer randomly from different parts of experiment field (one hectare) by stem counting method. Aphids were transferred to lab. The aphids were kept in petri-dishes under 20-22 °C, 60-70% humidity and daylight 16 hours conditions. The adult wasps emerged from aphid mummies and were counted and the percent of parasitism was calculated.

For confirmation, the adult wasps were sent to California (University of Davis)

The wasps were identified as *Aphidius ervi*,

on green alfalfa aphid and *praon palitans* on the spotted alfalfa aphid.

Our investigations showed that, the parasitism of *Aphidius ervi* on green alfalfa aphid has been 9-11% and the parasitism of *praon palitans* on spotted alfalfa aphid has been 12-20%.

20-202

TAXONOMY AND BIOLOGY OF THE THRIPS PARASITOID GENUS *CERANISUS* WALKER (HYMENOPTERA: EULOPHIDAE)

S.V. Triapitsyn, D.H. Headrick

Department of Entomology, University of California, Riverside, California, USA

Recent interest in biological control of thrips pests (Thysanoptera) brought to light several problems associated with the thrips-attacking Entedoninae (Eulophidae). The taxonomy of this genus is in a very poor state worldwide. The extremely small size and rarity of collection of these parasitoids has contributed to the lack of taxonomic activity and makes their identification by current workers difficult. Our objective is to clarify species issues in the genus *Ceranisus* Walker, examine the type material, and provide a key to the world species of *Ceranisus* and other noteworthy entedonines which are known to attack immature stages of thrips.

A review of the Nearctic species of *Ceranisus* has been completed (in press, Transactions of the American Entomological Society). One new species, *C. loomansi* S. Triapitsyn & Headrick, was described. Four other species of *Ceranisus* are redescribed and illustrated based mainly on a study of their type specimens as well as on additional material from the USA and Japan. Lectotypes are designated for *C. americensis* (Girault), *C. nubilipennis* (Williams) and *C. russelli* (Crawford). A key to eight species belonging to four entedonine thrips-attacking genera is given, and host associations are indicated for those species.

20-204

EFFECTS OF LINEAR FURANOCOUMARINS FROM CELERY ON TWO HOST-PARASITOID SYSTEMS: *TRICHOPLUSIA NI* - *COPIDOSOMA FLORIDANUM* AND *SPODOPTERA EXIGUA* - *ARCHYTAS MARMORATUS*

Stuart R. Reitz and John T. Trumble

Department of Entomology, University of California, Riverside, CA 92521 USA

Experiments were conducted to determine the impact of photoactivated linear furanocoumarins, present in celery (*Apium* spp.) and related plants on two host-parasitoid systems. We compared the development, size and survival of parasitoids reared from hosts fed diets containing linear furanocoumarins with those of unparasitized herbivores. One system consisted of the polyembryonic egg-larval parasitoid, *Copidosoma floridanum* (Ashmead) (Hymenoptera: Encyrtidae), reared from *Trichoplusia ni* (Hübner) (Lepidoptera: Noctuidae). The second system consisted of the solitary larval-pupal parasitoid, *Archytas marmoratus* (Townsend) (Diptera: Tachinidae) reared from *Spodoptera exigua* (Hübner) (Lepidoptera: Noctuidae). Increasing dietary concentrations of linear furanocoumarins prolonged larval development of *T. ni* but did not affect *T. ni* size or survival. However, increasing concentrations of furanocoumarins in the host's diet not only delayed development of *C. floridanum* but increased parasitoid mortality. In contrast to *T. ni*, increasing dietary concentrations of linear furanocoumarins increased the mortality of *S. exigua*. However, furanocoumarin concentration did not affect the size of surviving *S. exigua*. Increasing concentrations of furanocoumarins in the diet of *S. exigua* resulted in increased mortality of *A. marmoratus*. Similar to the effects on *S. exigua*, increasing concentrations of furanocoumarins did not affect the size of surviving *A. marmoratus*. Despite the prolonged larval development of *S. exigua*, there was no effect on *A. marmoratus* development time following host pupation.

These results suggest linear furanocoumarins have differential impacts on the two systems. The linear furanocoumarins did not affect polyembryonic development of *C. floridanum*, but were toxic to developing immatures. The linear furanocoumarins did not appear to be directly detrimental to *A. marmoratus*, but their impact was mediated through stresses to the host, *S. exigua*.

20-203

SEASONAL ABUNDANCE OF THE CITRUS LEAFMINER AND ITS PARASITOIDS IN FLORIDA CITRUS

J.E. Pena

Tropical Research and Education Center, University of Florida, Homestead, Florida 33031 USA

Seasonal abundance and parasitism of the citrus leafminer *Phyllocnistis citrella* Stainton, were investigated from summer 1993 through December 1995 on "Tahiti" limes in Florida. Citrus leafminer densities increased from spring through fall and declined during winter 1994 and 1995. Eight species of parasitoids attacked citrus leafminer immatures in commercial and experimental orchards. The eulophid *Pnigalio minio* (Walker), a primary ectoparasitoid of dipterous and lepidopterous leafminers, comprised about 80% of the parasitoids which emerged from *P. citrella*. Species and abundance of adult parasitoids varied considerably between leafminer generations. Based on the examination of 15,000 larvae and pupae of the leafminer, these parasitoids are apparently everywhere throughout the region, and parasitization rates exceeding 50 % have been observed in unsprayed groves. In general a positive correlation between leafminer populations and parasitoid densities demonstrated that indigenous parasitoids significantly reduced leafminer densities 2.5 years after its invasion of Florida.

20-205

THE TRENDS OF DIAMONDBACK MOTH PARASITOIDS ON CABBAGE IN RELATION TO DIFFERENT MIXED CROPS

Khuat Dang Long, Department of Insect Ecology Institute of Ecology & Biological Resources, National Centre for Natural Science & Technology, Nghia Do -Tu Liem Ha Noi -Viet Nam

Diamondback moth (DBM), *Plutella xylostella* (L.) is the most important pest on cabbage in North Vietnam. The population fluctuations and abundance of the pest were investigated weekly on cabbage (*Brassica oleracea* L., *B. gongilodes* L.) from November to March of two years 1992-1994. The investigations carried out in two localities of Red River Delta showed that of two important parasitoids reared from DBM, the pest pupae parasitized by the pupal parasitoid *Phaeogenes* sp. (Ichneumonidae) was very low (maximum 3.3%) in comparison with the sole larval parasitoid *Cotesia* (= *Apanteles*) *plutellae* Kurdj. (Braconidae) (average 30.8%).

It was found that cabbage fields adjacent to maize and rice fields often have significantly lower parasitized pest population by *C. Plutellae* than those on cabbage intermixed with different crops of Solanaceae, Fabaceae groups and some other decorative flowers (Asteraceae), for the maximal proportion of parasitized pest larvae was less than 25% (average 13.1%) on cabbage grown alone compared to percentage of parasitism up to 40% (average 17.7%) on the mixed planting cabbage with different crops.

In addition, cabbage fields of both above localities often treated by some pesticides as Cartap (PADAN 95BHN), Phethoate+Enthofenprox (CIDI M) but it was observed that the peak of parasitoid populations usually occurred in the middle and towards the end of the crop.

20-206

PARASITOIDS OF FRUIT-INFESTING TEPHRITIDAE—HOW TO ATTACK A CONCEALED HOST

R.A. WHARTON

Department of Entomology, Texas A&M University, College Station, TX USA

Fruit-infesting Tephritidae, exemplified by such economically important genera as *Anastrepha*, *Bactrocera*, *Ceratitis*, *Dacus*, and *Rhagoletis*, are remarkably diverse with over 1400 species world-wide attacking fleshy fruits. They, in turn, are attacked by a wide variety of parasitic Hymenoptera, including members of the families Braconidae, Chalcididae, Diapriidae, Eucilidae, Eulophidae and Pteromalidae. Although some are generalists, most species appear to be specific on Tephritidae. Further, extensive rearings of Tephritidae from fleshy fruits and from flower heads suggests that there is no overlap among the parasitoids attacking hosts in these two habitats. Among the opiine Braconidae, the most diverse group of parasitoids attacking fruit-infesting Tephritidae, there is a high degree of such habitat specificity even at the generic level. All known species of *Fopius* and *Diachasmimorpha*, for example, attack fruit-infesting Tephritidae. Interesting exceptions in the genera *Psytalia* and *Utes* are discussed. Knowledge of these relationships, and how they have evolved, is of particular value in predicting what types of host shifts can occur following importation for biological control.

Tephritid parasitoids exploit their hosts in a variety of ways. Egg-larval parasitism, with emergence from the host puparium, has been well-studied in *Fopius arisanus*, but occurs in several other opiines as well. The remaining opiines and all eucilids attack various larval instars, emerging from the puparium. Most of these oviposit through the fleshy portion of the fruit. At least some tetrastichine eulophids, however, attack the host directly, either by penetrating the fruit or by ovipositing on larvae as the latter emerge from fruit to pupate. Most fruit-infesting tephritids pupate in the soil, where they are subject to attack by chalcids and diapriids uniquely adapted for subterranean exploration. Though relatively few species have been studied in detail, critical examination of morphological features and a sound phylogenetic perspective should enable us to predict the attack strategies of most tephritid parasitoids.

20-208

EFFECT OF DIFFERENT COMBINATIONS OF TEMPERATURE ON THE REPRODUCTION OF *SPALANGIA GEMINA* BOUCEK (HYMENOPTERA, PTEROMALIDAE), PUPAL PARASITOID OF *MUSCA DOMESTICA* L. (DIPTERA, MUSCIDAE)V.A. Costa¹, E. Berti-Filho¹, J.R.P. Parra¹¹. Departamento de Entomologia-ESALQ/USP, Piracicaba, SP, Brazil

Spalangia gemina Boucek is one of the main parasitoids attacking pupae of *Musca domestica* L. and other synanthropic flies in poultry manure in the State of São Paulo, Brazil. This paper deals with the effect of different combinations of temperature on the immature and adult stages of *S. gemina* regarding the reproduction of this parasitoid on *M. domestica* pupae. The temperatures tested were 20, 25 and 30°C, 70 ± 10% relative humidity and 14 hour photoperiod. The temperature at which occurred the development of *S. gemina* did not affect the longevity of the females, but did influence their reproduction. Females from immatures reared at 30°C parasitized a lower number of *M. domestica* pupae and consequently produced lower progeny. The parasitism was more effective with females at 25°C, regardless the temperature conditions in which the immatures were reared.

20-207

MORPHOLOGICAL DEFENSE OF WHITEFLY NYMPHS AGAINST NATURAL ENEMIES

M. Guershon and D. Gerling

Department of Zoology, The George S. Wise Faculty of Life Sciences, Tel Aviv University, Tel Aviv, Israel

The effect of whitefly nymph's morphological features in the ecological context and especially their defensive role against natural enemies were investigated. Two whitefly species, *Bemisia tabaci* and *Aleyrodes singularis*, were chosen. *B. tabaci*, which is a major agricultural pest, also exhibits intraspecific, environmentally dependent, phenotypic variation (setose vs. smooth nymphs), which could be tested for its adaptive value for defense against predators. *A. singularis*, actively changes its innate phenotype by piling up on the nymphal dorsum exuviae and wax secretion. By removing these additions we could test for their possible defensive value when confronted with parasitoids and predators.

Significant effects of the different phenotypes on the interaction with natural enemies were found in both species. In the case of *B. tabaci*, a defensive effect was achieved when the setose phenotype developed on tomentose leaves. Indeed, we found that leaf tomentosity induces the setose phenotype. In *A. singularis*, the maximal defensive effect was achieved when both exuviae and the ovipositing mother were present on the patch of the developing whitefly nymphs. The mother continued to produce and spread wax upon the developing nymphs until they reached adulthood, a behavior that can be interpreted as parental care.

20-209

SURVIVAL OF THE FIRST AND SECOND COMERS IN SELF-SUPERPARASITISM AND CONSPECIFIC SUPERPARASITISM

Y. Y. Yamada, K. Miyamoto

Entomology Laboratory, Faculty of Bioresources, Mie University, Tsu, Mie 514, Japan

Using *Haplogonatopus atratus* (Hymenoptera: Dryinidae), a solitary parasitoid of the small brown planthopper, *Laodelphax striatellus* (Hemiptera: Delphacidae), we reveal the survival rates of the first-laid and second-laid offspring in superparasitism. Although it is usually impossible to distinguish between the first comer and the second comer in superparasitism, it is possible in this parasitoid because the immature parasitoid remains adherent to the oviposition point. Recording of the oviposition point and everyday observation of the superparasitized host clarifies the fate of the first comer and that of the second each. A healthy 4th-instar larva was parasitized within one day after molting. Then that larva was superparasitized 1, 2, 4, 8, 12, 24, 48, 72, or 96 hours later. Unmated parasitoid females were used for the experiment, i.e., eggs laid were all male, because there is a difference in the survival rate of the immature between the male and the female.

The survival rate of the first comer increased with increase of interval of the first and second ovipositions, while the survival rate of the second comer decreased, and consequently the survival rates of the two became similar for oviposition intervals of more than 1 day. For almost all intervals the survival rates of the first and second comers were each higher in conspecific superparasitism than in self-superparasitism. As a result, the proportion of hosts producing parasitoid adults was higher than that in solitary parasitism (60.0%) or almost the same, while in self-superparasitism the proportion was similar to the survival rate in solitary superparasitism or less than that.

20-210

INFLUENCE OF WHEAT AND OAT CULTIVARS ON THE DEVELOPMENT OF CEREAL APHID PARASITOIDS (HYMENOPTERA: BRACONIDAE)

E. Fuentes-Contreras¹, W. Powell², H.M. Niemeyer¹

¹ Departamento de Ciencias Ecológicas, Facultad de Ciencias, Universidad de Chile, Santiago, Chile - ² Entomology & Nematology Department, IACR-Rothamsted Experimental Station, Harpenden, U.K.

Wheat and oat cultivars with different levels of Hydroxamic acids, secondary metabolites involved in plant resistance against cereal aphids, were used to evaluate the influence of these compounds on the development of specialist and generalist aphid parasitoids attacking the host *Sitobion avenae* (Fabr.).

Higher Hx levels caused a significant increase in developmental time of the oligophagous parasitoid *Aphidius rhopalosiphii* De Steph., which is mainly accounted for by an increase in the parasitoid prepupal developmental time. However, the polyphagous *Ephedrus plagiator* (Nees) was not affected by Hx levels.

20-2012

THE BIOLOGY OF *ANAGYRUS DACTYLOPII* (HOW), (HYMENOPTERA: ENCYRTIDAE) ON *NIPAECOCCLUS VIRIDIS* (NEWSTEAD), (HOMO.: PSEUDOCOCCIDAE) IN SOUTHWEST IRAN.

Mossadegh, M.S. & V. Baniamiri

Department of Entomology, College of Agriculture, Shahid Chamran University, Ahwaz, Iran.

The mealybug, *Nipaecoccus viridis* (Niwstead) is one of the major pest of *citrus* spp. In Khuzestan southwest of Iran. The encyrtid parasitoid, *Anagyrus dactylopii* (How), parasitize up to 40% of the mealybug under the natural conditions. In a survey during 1994-95 the biological aspects as well as parasitoid/host interaction between *A. dactylopii* and *N. viridis* were studied at 26±2 C., 65±5%RH, and under a photoperiod of LD 14:12. The mealybugs were reared on pumpkin and sprouted potato tubers under the same conditions. *A. dactylopii* oviposits in all there nymphal and in the adult female stages of *N. viridis* when each stage was exposed separately. However, the frequency of hosts parasitized, and number of eggs deposited per host were significantly greater in third nymphal and adult female mealybugs than in either first or second stage nymphs. The sex ratio of female to male parasitoids was also the highest following oviposition in third nymphal and adult female host. The total developmental time (egg to adult) for male and female parasitoid were 12-15 ($\bar{X}=13.35\pm0.86$) and 13-16 ($\bar{X}=14.35\pm0.85$) days respectively. The developmental time of eggs, larvae and adults as well as sex ratio on three nymphals and adult stages were determined.

20-211

BIOLOGICAL CONTROL OF THE BLUE GUM PSYLLID, *CTENARYTAINAE EUCALYPTI* (MASKELL) (HOMOPTERA: PSYLLIDAE), IN CALIFORNIADahlsten, D. L., D. L. Rowney, W. A. Copper, R. L. Tassan, W. E. Chaney¹, K. L. Robb², S. Tjosvold³, M. Bianchi⁴ and P. Lane⁵

Center for Biological Control, University of California, Berkeley, CA USA - ¹ University of California Cooperative Extension, Monterey County, CA USA - ² U. of Calif. Cooperative Extension, San Diego County, CA USA - ³ U. of Calif. Cooperative Extension, Santa Cruz County, CA USA - ⁴ U. of Calif. Cooperative Extension, San Luis Obispo County, CA USA - ⁵ Sonoma County Dept. of Agric., CA USA

The blue gum psyllid was first discovered in Monterey County, California, USA in January 1991. Since the original find the blue gum psyllid has spread in a very short time throughout the California coastal area, and has become a major pest on *Eucalyptus pulverulenta* foliage plantations. Large amounts of pesticides have been used to control the psyllid in these plantations. One species of primary parasitoid wasp, *Psyllaephagus pilosus* Noyes (Encyrtidae) was found in Australia and New Zealand, and released at eight sites in California in spring/summer 1993. Psyllid populations declined somewhat at most sites in 1993 compared to 1992; in 1994 and 1995 psyllid populations had declined several hundred times below the pre-release levels, and were no longer a problem at all sites where parasitoid releases were made. The parasitoid has spread rapidly to other coastal areas and has controlled the psyllid levels in these areas in 1995.

20-213

HOST-FEEDING BEHAVIOR AND MATERNAL CARE IN *CEPHALONOMIA STEPHANODERIS* (HYMENOPTERA: BETHYLIDAE), AN ECTOPARASITOID OF THE COFFEE BERRY BORER.

G. Pérez-Lachaud.

El Colegio de la Frontera Sur, Tapachula, Chiapas, Mexico.

Cephalonomia stephanoderis Betrem is an ectoparasitoid of the prepupae and pupae of *Hypothenemus hampei* (Ferrari) (Coleoptera: Scolytidae), the most important pest of coffee worldwide. Although some studies have been done on its biology, the essential aspects of the behavior of this parasitoid have been neglected. In this work the host-feeding behavior and the influence of maternal care on brood survivorship were studied under laboratory conditions.

C. stephanoderis females remain with their brood after oviposition. Experimental removal of the mother influenced larval fitness: survival of broods guarded by the parental wasp was higher than that of broods without the attending mother (75% vs 45%). Moreover, most of larvae not attended by the mother failed to built a cocoon and the mortality of these naked pupae was higher (33% vs 15%). The behavior of the attending females was, nevertheless, influenced by their physiological state: starved females attacked their own eggs or larvae but the formation of a cocoon prevented the pupae from being fed.

By studying the influence of food on oögenesis, we were able to show that females which had not consumed a proteinaceous meal from the host body fluids were not able to mature eggs. Egg load (number of mature and developing oocytes present in the ovary of the female) influenced the oviposition behavior of *C. stephanoderis* females but had no influence on their feeding behavior. Host-feeding in *C. stephanoderis* is non-concurrent, wasps destroy the hosts from which they feed. Both the parasitic and predatory behaviors of *C. stephanoderis* females may be exploited to control *H. hampei*. This enhances the potential of this species as a biological control agent.

20-214

BIOLOGICAL CONTROL PROGRAM FOR AN INTRODUCED MEALYBUG, *ORACELLA ACUTA* (LOBDELL) (HOMOPTERA: PSEUDOCOCCIDAE), IN THE PEOPLE'S REPUBLIC OF CHINA

S.R. Clarke, J. Sun¹, G.L. DeBarr², C.W. Berisford¹

Forest Health, U.S. Forest Service, Lufkin, TX USA - 1
Department of Entomology, University of Georgia, Athens, GA USA - 2 Southern Research Station, U.S. Forest Service, Athens, GA USA

The mealybug *Oracella acuta* was introduced into Guangdong Province in the People's Republic of China (PRC) from the United States in 1988. Fifty hectares of slash pine forest were infested in 1990, increasing to 220,000 ha in 1995. The rate of spread is approximately 17-22 kilometers/year. Severe infestations are currently in exotic slash and loblolly pine plantations, but native Mason pine is also threatened. Pines are not killed, but growth and yield are reduced.

Populations in the U.S. are normally regulated at low levels by natural enemies, so a joint biological control project was initiated between the PRC and the U.S. to introduce natural enemies of *O. acuta* into the PRC. Parasitoids, including *Allotropa* sp. and *Acerophagus coccis* E. Smith, have been reared from greenhouse and field infestations of *O. acuta* in the southeast U.S. and shipped to Guangdong Province. The Chinese have released some parasitoids, and they are currently monitoring their establishment.

20-216

LARVAL AND PUPAL PARASITOIDS OF THE DIAMONDBACK MOTH, *PLUTELLA XYLOSTELLA* (L.) AND THEIR SEASONAL OCCURRENCE IN CABBAGE FIELDS IN NORTH JAPAN.

T. Noda, S. Miyai, K. Konishi¹

Tohoku National Agricultural Experiment Station, Morioka Iwate, Japan
- 1 National Institute of Agro-Environmental Sciences, Tsukuba Ibaraki, Japan.

Seven primary parasitoids, three facultative secondary parasitoids, and seven secondary parasitoids were recorded from larvae and pupae of the diamondback moth *Plutella xylostella* in cabbage fields in North Japan. Among the primary parasitoids, *Cotesia plutellae*, *Diadegma niponica*, *Diadromus subtilicornis*, and *Oomyzus sokolowskii* were dominant. *O. sokolowskii* was also the parasitoid of *C. plutellae*, i.e. the secondary parasitoid of *P. xylostella*.

The density of 4th-instar larvae of *P. xylostella* per plant started to increase in late June in 1994 and 1995, and abruptly decreased in early August after showing a peak in July. The occurrence of the pupae showed the same pattern with several days delay. The parasitism of the 4th-instar larvae by *C. plutellae* and *D. niponica* was observed as early as in late May, but *D. niponica* disappeared in middle July. The parasitism of the 4th-instar larvae by *C. plutellae* and *O. sokolowskii* and that of the pupae by *D. subtilicornis* increased in late July when the host density decreased. The parasitism in the pupae continued to be more than 40% from early August to middle November, so that the density of *P. xylostella* seemed to be kept low after August.

20-215

INFLUENCE OF THE DEFENSIVE BEHAVIOUR OF THE CITRUS BROWN APHID, *TOXOPTERA CITRICIDUS* (KIRKALDY) (HOMOPTERA: APHIDIDAE) ON THE PRECISENESS OF THE HOST DISCRIMINATION BY ITS PARASITOID, *LYSIPHLEBUS JAPONICUS* ASHMEAD (HYMENOPTERA: APHIDIIDAE).

M. Takanashi

Laboratory of Entomology, Kuchinotsu Branch, Fruit Tree Research Station, Ministry of Agriculture, Forestry and Fishery, Kuchinotsu, Nagasaki, Japan

The brown citrus aphid *Toxoptera citricidus* (Kirkaldy) jerks up and swivels its abdomen when it is attacked by an Aphidiid parasitoid *Lysiphlebus japonicus* Ashmead. Once the swiveling was initiated in a part of a colony, it could quickly propagate the same synchronous movement among other individuals which had not been attacked by the parasitoid. The effect of this group defense on the oviposition success of the parasitoid was more obvious in older aphids. When a parasitoid allowed to attack in a colony consisting of each ten 1-day-old parasitized (1 hour before) and unparasitized aphids, it could precisely discriminate unparasitized hosts from parasitized ones. It was observed that the parasitoid used both external (by drumming) and internal (by light stabbing) markers in the course of host discrimination. On the contrary, when the same experiment was undertaken using 5-day-old (more defensible) aphids, the frequency of superparasitisms by the parasitoid increased significantly. Since no difference is expected in the outcome of intra-specific competition of the parasitoid larvae between the two host ages, the high frequency of superparasitisms in the colony of 5-day-old aphids seemed not to be ascribed to parasitoids' decision but to be the result from stronger disturbance effect of group swiveling on the discrimination process of the parasitoid.

20-217

A. *CLAVICORNIS*, A STEPPING STONE IN THE EVOLUTION OF PARASITOID BEHAVIOR IN THE ROVE BEETLE GENUS *ALEOCHARA* (COLEOPTERA: STAPHYLINIDAE)

K. Peschke, D. Fuldner¹, B. Mittmann

Institut für Biologie I (Zoologie), Universität Freiburg, Germany. ¹Zoologisches Institut I, Universität Würzburg, Germany.

Larvae of the genus *Aleochara* live as solitary ectoparasitoids on pupae of cyclorrhaphous diptera within the puparium. Morphological and behavioral adaptations to host finding, orientation on the host, gnawing an entrance hole into the puparium shell, avoidance of competition, site and mode of pupation have been comparatively investigated in numerous species of different subgenera.

A. (Heterochara) clavicornis has free roaming larvae with quite different morphology (all campodeoid in contrast to eruciform L2 and L3 in other *Aleochara* species). The predaceous larvae of are capable to overwhelm migrating blow fly maggots and to feed upon unupated and pupated hosts as well. They are also able to move between hosts of different stage and occasionally feed in groups.

Evolutionary tendencies in the parasitoid life habit and the phylogeny of the genus are discussed.

20-218

BIOLOGICAL CONTROL OF THE CHESTNUT GALL WASP IN JAPAN UTILIZING A PARASITOID IMPORTED FROM CHINA (HYMENOPTERA: CYNIPIDAE-TORYMIDAE)

Y. Murakami

Institute of Biological Control, Faculty of Agriculture, Kyushu University, Fukuoka, Japan

As a biological control agent of the chestnut gall wasp, *Dryocosmus kuriphilus* Yasumatsu, a parasitoid, *Torymus (Syntomaspis) sinensis* Kamijo was imported from China, and it was released in Tsukuba, Ibaraki, central Japan, and Ohzu, Kumamoto, southwestern Japan in 1982. After establishment, the parasitoid population increased, and the host cynipid galls decreased under EIL by 1988 in Ibaraki. While, in Kumamoto, the parasitoid population had not increased in six years following its release but has increased since 1989, reaching a level of 28 % in parasitism in 1995. Two factors might play an important role in the delay in the increment of the parasitoid; the low female sex ratio during several years after establishment, and high mortality associated with the activity of native facultative hyperparasitoids.

20-219

EFFECTS OF PUPAL EXTRACT OF *GALLERIA MELLONELLA* ON DEVELOPMENT OF AN ENDOPARASITOID, *VENTURIA CANESCENS* (GRAVENHORST) (HYMENOPTERA: ICHNEUMONIDAE)

Y. Nakahara, K. Iwabuchi, J. Mitsuhashi
Faculty of Agriculture, Tokyo University Agr. & Tech., Fuchu Tokyo, Japan

Venturia canescens was reared from egg to pupa on a semi-artificial diet containing pupal extract of *Galleria mellonella*. *G. mellonella* pupae were heated at 60 °C for 10 min and homogenized with the same amount of MGM-450 insect cell culture medium. After centrifugation, the supernatant was sterilized by filtration, and used as a diet. Diets were prepared from the pupae of 0, 1, 2 and 3-day old. On all the diets, 48 h-old *V. canescens* eggs developed to the last instar (5th instar). The extract from 1-day old pupae was the most effective, and supported the development of 90 % of larvae to the last instar, however, none of the larvae became pupae unless the diet was frequently renewed, and obtained pupae did not emerge. Pre-germ band stage-eggs of the parasitoid, within 4 h after oviposition, also developed successfully on this diet and 2 out of 62 pupated. The growth promoting ability of *G. mellonella* extract was lost by heat treatment at 80 °C for 10 min or by passing it through molecular sieve of 30,000 or 100,000 M.W.

20-220

FIELD EVALUATION OF IN VITRO REARED *CATOLACCUS GRANDIS* (HYMENOPTERA: PTEROMALIDAE) AS A BIOLOGICAL CONTROL AGENT OF THE BOLL WEEVIL (COLEOPTERA: CURCULIONIDAE)

J. A. Morales-Ramos, M. G. Rojas, E. G. King

U.S. Department of Agriculture-ARS, Subtropical Agricultural Research Laboratory, Weslaco, Texas USA.

The efficacy as a biological control agent of the ectoparasitoid *Catolaccus grandis* (Burks) females reared in a solid artificial diet was evaluated in South Texas. For the first time in the United States, field releases of an in vitro reared parasitoid were done using a diet formulated without the use of insect components. Percent parasitism observed in the field during May, 1994 was 55.6, 57.3, and 39.4% during the second, third, and fourth weeks of releases, respectively.

The searching capacity and dispersal ability of in vitro reared *C. grandis* were compared with in vivo reared parasitoids under field conditions in South Texas in 1995. There was not significant difference in the incidence of parasitism inflicted by in vitro and in vivo reared *C. grandis* to boll weevil larvae distributed within a 30m and 60m radius from the release point. Boll weevil life tables calculated from cohorts placed within 15 and 45m from the release point showed no significant differences in mortality induced by parasitism by in vitro and in vivo reared *C. grandis*. These results indicate that the use of artificial diets to mass produce quality *C. grandis* is promising.

20-221

PARASITIDS OF *HELICOVERPA ARMIGERA* (HBN.) (LEPIDOPTERA: NOCTUIDAE) ON GREENHOUSE TOMATO CROPS IN THE OESTE REGION OF PORTUGAL. A PRELIMINARY STUDY.

E. Figueiredo, A. Mexia

Secção Autónoma de Protecção Integrada, Instituto Superior de Agronomia, Lisboa, Portugal.

As a result of larval collection of tomato fruitworm, *Helicoverpa armigera* (Hbn.), on greenhouse tomato crops in order to diagnose eventual insect diseases and to obtain larvae for laboratory rearing, high levels of parasitism were recorded in greenhouses under IPM schemes, in some cases almost controlling the pest, in contrast to greenhouses with traditional chemical pest management.

The parasitoid complex was determined and compared with other references of parasitism of the tomato fruitworm, in greenhouse and outdoors crops, in Iberian Peninsula and northern Africa to discuss its importance. The role of this parasitism in greenhouse IPM programs, in the Oeste and in other regions, is also evaluated.

20-222

DIGLYPHUS POPPOEA WALKER (HYM: EULOPH.) AS AN IMPORTANT NATURAL CONTROL AGENT OF *LIRIOMYZA HUIDOBRENSIS* (BLANCHARD) (DIPT.: AGROMYZIDAE) IN PORTUGAL

Maria Godinho & António Mexia - Secção Autónoma de Protecção integrada, Instituto Superior de Agronomia, Tapada da Ajuda, Lisboa

Recent studies on leafminers in Portugal, conducted in some greenhouses in the Oeste region, approximately 40-50 Km north of Lisbon, allowed the characterization and evaluation of the leafminers parasitoids population.

The hymenopterous parasitoids were reared from *Liriomyza huidobrensis* (Blanchard) larvae sampled from greenbeans, lettuce, tomato and pepper.

In 1993 about 39% of the samples revealed the presence of *Diglyphus poppoea* Walker. During 1994 and 1995 this species had similar representativity and was present all over the year. The relative importance as natural control agent is presented and its abundance is discussed, taking into account the differences between the greenhouses where the samples were taken.

20-224

DISTRIBUTION AND DORMANCY OF THE PARASITIDS ATTACKING *CHROMATOMYIA FUSCULA* (ZETTERSTEDT) (DIPTERA : AGROMYZIDAE) IN NORWAY

N.Trandem
Department of Biology and Nature Conservation, Agricultural University of Norway, Ås, Norway.

The larvae of *Chromatomyia fuscula* mine the leaves of cereals and other grasses, and the species is a cereal pest in parts of Norway. It pupates in the leaf, and has one generation per year (adults overwintering). It is attacked by chalcid (Eulophidae and Pteromalidae) and braconid (Braconidae) parasitoids.

In July - Sept. 1994, barley leaves with mines were collected from 18 fields, ranging from 58 to 69.5°N and from 5 to 540 m above sea level. The parasitoids emerging from the leaves were identified and counted, followed by an inspection of each mine. The number of species in a sample of 45 leaves ranged from 1 to 9 (mean=4.6) and decreased with the latitude and increased with the number of specimens (mean number=48). The most numerous parasitoid was *Cyrtogaster vulgaris* (Walker) (Pteromalidae), a pupal parasitoid overwintering as an adult. It was not found in the three highest (>300m), nor in the three northernmost (>65°) localities.

The mine inspection revealed dormant parasitoid larvae in 80% of the localities north of 60° (N=11). These larvae were kept at about 5°C over winter, and adults of at least 6 different species, both larval and pupal parasitoids, emerged the following spring. Further south these species emerge in the late summer. North of 60° they seem to have a mixed strategy (i.e. they were found both as newly emerged adults and as larvae in the autumn under lab conditions).

20-223

SYNTHESIS OF A TERATOCYTE-SPECIFIC PROTEIN IN THE BRACONID WASP, *PERILITUS COCCINELLAE* SCHRANK (HYMENOPTERA: BRACONIDAE)

K. Kadono-Okuda, T. Okuda

Department of Insect Physiology and Behavior, National Institute of Sericultural and Entomological Science, Tsukuba, Ibaraki, Japan

During parasitism, *Perilitus* teratocytes became hypertrophic and enlarged about ten-fold in diameter from 50 to 500 µm on average. The increase in protein content of the teratocytes mirrored the increase in protein synthesis rate. Non-denaturing-PAGE revealed that the teratocytes contained a major polypeptide with a high molecular weight of about 540 kDa. The teratocytes were cultured in vitro in a medium containing ³⁵S-methionine. Both the proteins from the incubated teratocytes and the medium were subjected to PAGE followed by fluorography. The fluorogram revealed that the teratocytes synthesized the 540 kDa protein. The teratocytes had a tendency to accumulate the synthesized teratocyte proteins without release. We clarified the possibility of the active secretion by a pulse-chase experiment. Finally, we discuss a possible function of the teratocytes in *P. coccinellae*.

20-225

MALAISE CATCHES OF CHALCID PARASITIDS OF THE LEAFMINER *CHROMATOMYIA FUSCULA* (ZETTERSTEDT) (DIPTERA: AGROMYZIDAE) DURING FOUR YEARS IN AN ORGANIC BARLEY FIELD AND ITS SURROUNDING VEGETATION.

E. Hågvar¹, T. Hofsvang², K. Grendstad¹

¹ Department of Biology and Nature Conservation, Agricultural University of Norway, Box 5014, N-1432 Ås, Norway. - ² The Norwegian Crop Research Institute, Plant Protection Centre, Department of Entomology and Nematology, N-1432 Ås, Norway.

The leafminer *Chromatomyia fuscula* is an annual pest in cereals and grasses in Norway. Malaise traps were placed in an organically managed barley field and in the surrounding vegetation at Ås, southern Norway, in 1992-95. The chalcid parasitoid species which we previously had reared from *C. fuscula* on barley were sorted out.

The total number of chalcid parasitoid specimens in the traps varied considerably from year to year. Each year the traps collected about 9-14 of the ca 15 species totally reared from the leafminer. The dominant species alternated between the pupal parasitoid *Cyrtogaster vulgaris* (Walker) (1993, 1995) and the larval parasitoid *Diglyphus begini* (Ashmead) (1992 in the field, 1994). *D. begini* had a higher relative frequency in the field compared to the edge area, whereas the opposite was the case for *C. vulgaris*. Each year, at least one of these two species also dominated the parasitoid complex that emerged from barley samples infested with the leafminer.

The phenology and sex ratio are shown for some dominant species.

20-226

INTER- AND INTRASPECIFIC VARIATION IN *EUBAZUS* SPP. (HYMENOPTERA: BRACONIDAE) PARASITOIDS OF *PISSODES* WEEVILS (COLEOPTERA: CURCULIONIDAE)

M. Kenis

International Institute of Biological Control, European Station, Delémont, Switzerland.

Eubazus spp., egg-prepupal parasitoids of *Pissodes* weevils, are considered as potential biological control agents against the white pine weevil, *Pissodes strobi* (Peck), in North America. In Europe, three closely related species exist, with separate microhabitat affinities: *Eubazus semirugosus* (Nees) is a parasitoid of *Pissodes* spp. in pine trunks, *E. robustus* (Ratz.) attacks *P. validirostris* (Sahlberg) in pine cones, and an undescribed species parasitises *P. piceae* (Ill.) in fir trunks. Populations of these species were compared in traits likely to affect establishment or control by biological control agents. Variation between species was found in development time, diapause, host preference, fecundity and functional morphology. Intraspecific variability was observed in diapause requirement between climatic biotypes of *E. semirugosus* and *E. robustus*. Differences observed within, and between *Eubazus* spp. are regarded as an adaptation to the biology of their respective hosts. Implications of these differences in the biological control of *P. strobi* are discussed.

20-228

HOST AGE PREFERENCE AND FUNCTIONAL RESPONSE IN AN ECTO PARASITOID, *HEBROBRACON HEBETOR* SAY (HYMENOPTERA: ICHNEUMONIDAE).

P.N. Patel, A.T.B. Cecílio

Departamento de Zoologia, Instituto de Biologia, Universidade Estadual de Campinas, Campinas - SP. Brasil

Through analysis of variance it was observed that parasitoid females paralyzed host larvae indiscriminately when offered *Anagasta kuhniella* (Zeller) larvae of 3 different ages daily for four consecutive days, since emergence. They did not present significant preference in relation to the day of offering ($p = 0.267$) and the size of host larvae ($p = 0.073$). On the contrary, significant differences were observed in average number of larvae parasitized in relation to the day of offering ($p = 0.049$) (2nd and 3rd day) and the age ($p = 3.578 \times 10^{-5}$) (5th instar) of host larvae. These results indicate that the female parasitoids ensure the oviposition sites by paralyzing maximum number of larvae but deposit the eggs preferentially in the larger larvae.

Functional response of *Hebobracon hebetor* say was analyzed at 10 (5, 10, 15, ..., 50) different host densities in relation to 3 distinct behaviors of females: number of larvae paralyzed, number of larvae parasitized and number of eggs deposited. A type I functional response was exhibited by the female parasitoid in response to host density only in case of number of larvae paralyzed. These informations are important for mass-rearing of *H. hebetor*, for biological programs against *A. kuhniella*

20-227

SURVEY OF NATURAL ENEMIES OF *Spodoptera frugiperda* IN THE SOUTH OF BRAZIL¹
F.H. Valicente¹

¹ EMBRAPA/CNPMS - Brazilian Agricultural Research Corporation - Sete Lagoas-MG, Brasil.

A survey of natural enemies of fall armyworm, *Spodoptera frugiperda*, was done in maize producing region, in South of Brasil, during 1992/93 and 94/95 years. Insects were collected in 5 different places, and in each place 2 different maize crops were selected. In each maize crop about 90 larvae were collected. All larvae were brought to the laboratory, fed with artificial diet and observed daily. Results showed that the parasitoids were basically the same, varying the frequency depending on the place. The same was observed in relation to viruses. *Campoletis grioti* (Hymenoptera: Ichneumonidae) and *Archytas marmoratus* (Diptera: Tachinidae) were the most frequent parasitoids. *Campoletis grioti* sometimes occurred in 47% of the sampled larvae, and *A. marmoratus* in 15% of the sampled larvae. *Eiphosoma vitticollis* (Hymenoptera: Ichneumonidae) was also found parasitizing *S. frugiperda* larvae, but at low levels. *Baculovirus* showed a high natural incidence in some places killing up to 10% of the larvae. Only one granulosis virus was found. The fungi *Nomuraea rileyi* occurred only in one place attacking 10% of the larvae. Some diptera and hymenoptera died during the larval stage and were not identified.

20-229

MICROCHAROPS ANTICARSIAE GUPTA (HYMENOPTERA: ICHNEUMONIDAE) AS A DISSEMINATOR OF ENTOMOPATHOGENIC FUNGUS *NOMURAEA RILEYI* (FARLOW) SAMSON AND ITS EFFECT ON THE DEVELOPMENTAL STAGES OF PARASITOID.

P.N. PATEL, S.P. DE SOUZA, C.M. SILVA

Departamento de Zoologia, Instituto de Biologia, Universidade Estadual de Campinas, Campinas - SP. Brasil

Under laboratory conditions, when female ovipositors were contaminated manually and with fungus hyphae, they were unable to transmit the infection to host (*Anticarsia gemmatilis* Hüb.) larvae.

Different concentrations of fungus affected the duration time of larval ($F=29.692$; $df=4$; $p<0.01\%$) and pupal ($F=15.335$; $df=4$; $p<0.01\%$) stages. Only high concentration, 1.97×10^6 of viable spores affected the emergence of parasitoid larvae from host ($\chi^2=31.4058$; $P<0.1\%$). To verify the effect of infection on the development of parasitoid larvae; host larvae were first parasitized at different time intervals such that on the day of inoculation 0, 1, 2, 4 and 8 days parasitized larvae were present. Parasitoid cocoon formation did not suffer significant reduction ($\chi^2=3.77$; $df=1$; $p=5.31\%$) only in hosts parasitized 8 days prior to inoculation. Effects of fungus on the developmental stages of parasitoid revealed that *N. rileyi* has a negative effect on parasitism of *M. anticarsiae* in host larvae. Moreover such effects reflect in the suppression of parasitism as well as it delays the development of parasitoid in the host larvae.

Financed by FAPESP (Nº 92/5198) and CNPq (Nº 510061/93)

20-230

ADAPTIVE UTILIZATION OF HOST RESOURCE BY EULOPHID PARASITOIDS OF LEAF-MINING FLY

T. Sugimoto

Entomological Laboratory, Faculty of Agriculture, Kinki University, Nara, Japan

The leaf-mining larvae, *Phytomyza ranunculi* Schrank, are parasitized by more than ten species of eulophids in Japan. These eulophids parasitize hosts after killing them.

Such a parasitization pattern will lead to the limited supply of resource to their progeny within the host and, in fact, decreased the fitness of their progeny, especially obtained from young hosts; for example its decreased body-size, longevity and fecundity. Eulophid females often sucked host fluid through the small opening produced by their ovipositor in the epidermis which covers the host mine. This always led to the death of hosts. The ratio of killed hosts by host feeding and parasitization was 1:2 to 1:1 on the average through their life. They were unable to live long and to initiate oogenesis without a supply of the energy by host feeding, probably because they allocate most of the limited supply of energy from the killed host toward a construction of their body, so store less energy as an adult. Thus, they supply such a deficiency of saprophaga in their larval stage by an adaptive utilization of hosts as follows.

First, they preferred young hosts with a low quality for host feeding and mature hosts with a high quality for parasitization. Also, they laid preferentially a male egg in young hosts but a female egg in mature hosts.

20-232

OCCURRENCE AND CONTROL OF BEET ARMYWORM, *SPODOPTERA EXIGUA* HUBNER (LEPIDOPTERA: NOCTUIDAE), USING SYNTHETIC SEX PHEROMONE IN KOREAJong Dae Park, Kyu Chin Kim¹

Research bureau of Chonnam Rural Development Administration Naju, Korea -¹ Department of Agrobiolgy, Chonnam National University, Kwangju, Korea

This study was carried out to investigate seasonal occurrence of the Beet armyworm(BAW) *Spodoptera exigua*, and on suppress of their density collected by mass trapping method and control effect in field using mating disruption dispenser of synthetic sex pheromone in Korea from 1992 to 1994. Adults males of BAW were collected by pheromone from early April through early November. The numbers began to increase abruptly from early July, and forming three peaks on mid. July, early August and early September. In control effects using mass trapping methods, number of leaves damaged by BAW were 0.2-3.0 individuals per 60 hills of *Allium fistulosum* comparing with 33.2 individuals at non-treated field. Also, the number of male adults attracted to the pheromone were 1.8-5.0 individuals at the beginning of installation but increased gradually afterward. There was a negative correlation between amount of male adults attracted to the pheromone and number of damaged leaves($r=-0.9572^*$). Densities in egg and larva of BAW in field treated with mating disruption dispensers was 1.9% level of that without dispensers in welsh onion in 1993. Also, 5.9% and 5.2% were counted from 10ha and 20ha of welsh onion field comparing with fields without dispensers in 1994. Rate of damages in welsh onion fields were 1.6% and 3.0% level in 10ha and 20ha, respectively, and control value were maintained at 80% level until harvest date, October.

20-231

LARVAL PREDATORY BEHAVIOUR OF THE ECTO-PARASITOID *DIGLYPHUS ISAEA* (WALK.) (HYMENOPTERA: EULOPHIDAE)

G. Nicoli, G. Celli

Istituto di Entomologia 'G. Grandi', Università di Bologna, Italy

Diglyphus isaea (Walk.) is a palearctic parasitoid widely used in Europe for biological control of the nearctic leafminer *Lirionomyza trifolii* (Burg.) (Diptera: Agromyzidae). Adult female paralyzes the host larva before oviposition and lays one egg (exceptionally 2-5) nearby; it is generally described as a 'facultatively gregarious ecto-parasitoid'. Three experiments were carried out using third-instar larvae of *L. trifolii* (infesting bean leaves) as hosts. In the first experiment (n=98), several adult females were placed on a leaf containing one host larva to induce superparasitism. The newly-hatched parasitoid larvae soon started to explore the neighbourhood, killing the other parasitoid eggs or cannibalising each other. Two days later, gregarism was still occurring in 16.3% of hosts, but a maximum of one parasitoid pupated per host. In the second experiment (n=40), over-infested leaves were used with several *L. trifolii* larvae of different ages and wide interconnections of mines. *D. isaea* was allowed to paralyse only one host and lay only one egg. The newly-hatched larvae explored the microhabitat: some of them (30.0%) met an active *L. trifolii* larva and killed it for feeding in 50.0% of meetings. In the third experiment (n=29), some parasitoid larvae cohabited with several host larvae, that could be active, only paralysed (n=139 in total) or parasitized (n=132 in total). Cannibalism was recorded in 30 cases (22.7% of parasitized larvae); predation of active larvae occurred 18 times and *D. isaea* larvae left the original host to move to another paralysed larva in 12 cases. From the first to the third experiment, development time decreased for both sexes, female length increased (1.27 ± 0.37 , 1.33 ± 0.24 , 1.46 ± 0.24 mm respectively; means±ds) and adult emergence (35.7%, 62.5% and 80.3% of parasitized larvae respectively) increased too. These findings indicate that *D. isaea* is a 'solitary ecto-parasitoid' and that the double role of parasitoid-predator within the peculiar microhabitat of a over-infested leaf can improve the fitness of the larvae, also explaining the strong propensity of adult females to paralyse hosts in excess when placed with a high number of *L. trifolii* larvae.

20-233

INCIDENCE OF PATHOGENS AND PARASITOIDS OF *Anticarsia gemmatilis* (LEPIDOPTERA: NOCTUIDAE) PRE-IMAGINAL IN A SOYBEAN (*Glycine max*) AGROSYSTEM, RS, BRASIL.

M.C.G.P. de Araújo and I.B.M. Da Cruz

Departamento de Biologia e Química, Universidade Regional do Noroeste do RS/UNIJUI, Ijuí, Brasil.

Information about damage potential to soybean by the soybean caterpillar (*Anticarsia gemmatilis*) is necessary before we can establish the control level. This study employed the life systems analysis of *A. gemmatilis* and their natural enemies. (pathogens and parasitoids). The pre-imaginal stages were collected twice a week in the agricultural year 1995/1996. Ten different plant samples were alleatoty collected and they were checked for the egg's presence in the leaveslets. The caterpillars were captured by the Sheppard's Method and analysed under laboratory conditions (14L:10D; 25°C; 70%RH). The results showed differents frequencies of parasitoids and pathogens in eggs, caterpillars and pupae related with fenological plant stage. The egg's parasitoid was only *Trichogramma pretiosum*. In the larval stages, we observed 81% mortality caused by diseases, 18% by parasitoids and 1% by others ones. The diseases more frequent were *Entomophthora* sp (40%) and *Baculovirus anticarsia* (21%) and the parasitoid observed was *Microcharops* sp (Hymenoptera). In the pupal period 89% of mortality detected was caused by Tachinidae. The statistical analysis showed correlation between the plant fenology, the frequency of the three principal pre-imaginal stages of Noctuidae and the incidence of their natural enemies.

20-234

HOW TO RECOVER BENEFICIAL PARASITOIDS OF THE ALFALFA SEED CHALCID, *BRUCHOPHAGUS RODDI* GUSS. (HYMENOPTERA: EURYTOMIDAE) FROM THE "GARBAGE" ?

G. Szócs, Cs. Erdélyi, Gy. Makranczy, A. Bus¹

Plant Protection Institute, Hungarian Academy of Sciences, Budapest, Hungary - 1 National Inspectorate for Seed and Vegetative Reproduction Material, Budapest, Hungary

The seed-boring larvae of the alfalfa seed chalcid, *Bruchophagus roddi* Gussakovsky (Hymenoptera: Eurytomidae) can cause damage up to 80% in the production of alfalfa sowing-seed. The larvae of this pest host a number of beneficial parasitoids, which are in the stage of diapausing larva at the time of commercial seed-harvest. At commercial seed cleaning, seeds with a diapausing parasitoid larva inside go to the chaff, and they will be eliminated with the chaff. We suggest recycling beneficial parasitoids from this natural reservoir in order to use them as biocontrol agents against the alfalfa seed chalcid. A simple method to re-gain the beneficial parasitoids from the chaff, to store them until use, and to let them emerge is proposed. Possibilities to separate beneficial parasitoids from their non-parasitized hosts are discussed.

20-235

MATING STRUCTURE AND SEX RATIO IN A SEED EATER BRACONID WASP *ALLORHOGAS DISPISTUS* AND IN ITS PARASITOID *EURYTOMA* SP (EURYTOMIDAE)

M. V. Macêdo^{1,2}, M. C. P. Pimentel², M. P. Silveira² & T.M. Lewinsohn¹

¹ Lab. Interações Insetos-Plantas, Depto Zoologia, Universidade Estadual de Campinas, Campinas, SP, Brasil. * Pós Graduação em Ecologia, Bolsista CAPES.

² Lab. Ecologia de Insetos, Depto Ecologia, Universidade Federal do Rio de Janeiro, Rio de Janeiro, RJ, Brasil

Larvae of *Allorhogas dispistus* feed on developing seeds of *Pithecellobium tortum* (Leguminosae) an abundant and widely distributed shrub in the coastal scrub (restinga) of Barra de Maricá, Maricá County, Rio de Janeiro State, Brasil. These larvae can be parasitized by the solitary parasitoid *Eurytoma* sp. In order to describe the mating structure and the sex ratio of both species, 551 fruits from 13 plants were collected from June to August 1995, and observed daily for adult emergence. In all 1751 braconids and 3991 eurytomids were obtained. In both species males tend to emerge earlier than females. *A. dispistus* aggregated in groups of up to eight males waiting for each emerging female showing no aggressive behavior. *Eurytoma* sp males also wait for emerging females but males are very aggressive and only one wins the contest. In both species only mated females disperse. These observations are consistent with the Local Mate Competition hypothesis (Hamilton, 1967; Science 156: 477-88) from which we would expect a female biased sex ratio. However, summing all insects that emerged throughout the whole season the real sex ratio is 1:1 both for the braconid and the eurytomid. This can be explained by the observed male dispersal from the natal patch, which would put this case into the intermediate mating structure category, especially in this case where patches are abundant and widely distributed.

20-236

HOST-PARASITOID RELATIONSHIP IN ENTOMOGENOUS GALLS IN *PAULLINIA CARPOPODEA* (SAPINDACEAE) IN THE SOUTHEAST BRAZIL

M. M. Saavedra, M. A. P. Azevedo & R. F. Monteiro

Laboratório de Ecologia de Insetos, Departamento de Ecologia, Inst. Biologia, Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brasil

Very little is known about the ecology of galls and their associated insects in the neotropical regions. In an Atlantic Forest ecosystem in the Southeast Brazil we found 11 different types of entomogenous galls in *Paullinia carpopodea*. Nothing has been recorded in the literature about these or any other galls from this plant species. Our objective was to describe the composition, dynamics and structure of these galls and their associated insects.

Twenty plant individuals were twice a month checked for galls. Some of these galls were collected for morphological analyses and to obtain the insects in the laboratory. Most of the galls were found throughout the year, possibly due to the constant production of new leaves, which was observed.

Ten types of galls are induced by Cecidomyiidae (Diptera) from which we obtained 28 wasp species belonging to 7 different families: Eulophidae (64%); Eurytomidae (18%); Mymaridae, Trichogrammatidae, Pteromalidae, Encyrtidae and Scelionidae (18% all together). The Eulophidae predominance in the gall parasitoid guild has been observed in other studies in this region, and it is quite different from data available for the nearctic region. If the parasitoid species represented by a single individual were excluded, it would be found that 70% (12 species) of them occur in only one type of gall, that is, they are probably specialists in this system.

From only one type of gall, there were 54% of the insect species. This high diversity can be explained by its high abundance and complexity caused by phytophagous agents acting as gall modifiers (endogall).

20-237

MUSCA DOMESTICA L. 1758 AND ITS PARASITOIDS IN SOUTHEASTERN BRAZIL.

M.A.F. Almeida¹, A. P. Prado¹

¹ Instituto de Biologia, Departamento de Parasitologia, Universidade Estadual de Campinas, Campinas, Brazil.

A survey was conducted to verify sazonal abundance of *Musca domestica* L. and its parasitoids, in microhabitats of a dairy cattle farm. *Spalangia cameroni* Perkins, *S. endius* Walker, *S. nigroaenea* Curtis, *S. gemina* Boucek and two species of *Muscidifurax* (Hymenoptera: Pteromalidae) were found associated with *M. domestica*. Larvae of *Aleochara puberula* (Klug) (Coleoptera: Staphylinidae) also emerged from *M. domestica* puparia and these larvae were kept in conditions of laboratory to wait the emergence of adults. *A. puberula*, *S. cameroni* and *S. endius* were the most important species parasitizing *M. domestica*, although they showed different sazonality. The population of *M. domestica* was influenced by temperature and precipitation, but parasitoid species were influenced by the flies density, showing the possibility that could be a density-dependence relationship.

20-238

THE USE OF LIFE TABLES IN ASSESSING THE ROLE OF INSECT PREDATORS AND PARASITIDS AS MORTALITY FACTORS OF THE APPLE ERMINE MOTH, *YPONOMEUTA MALINELLUS* (LEPIDOPTERA: YPONOMEUTIDAE)

U. Kuhlmann

International Institute of Biological Control, European Station, Delémont, Switzerland

The apple ermine moth (AEM), of European origin, was accidentally introduced into British Columbia and Washington State in 1981 and developed into a serious pest of apple trees. The larvae of *Yponomeuta malinellus* ZELLER feed in characteristic tents monophagous on apple leaf clusters and may defoliate entire trees during heavy infestations, thus causing economic losses.

In Europe, AEM are attacked by a large number of natural enemies. Life table studies including fertility estimates of AEM were carried out to understand the role of natural enemies in controlling the pest in Europe. From the parasitoid community of *Y. malinellus* in Germany 7 different primary parasitoid species were obtained, which belong to 4 different parasitoid guilds attacking distinct niches in the life cycle of AEM. Life tables indicate that insect egg predators in the present study were abundant and that the impact of these predators reached 34.9% in 1993, 37.0% in 1994, and 50.8% in 1995 of the total generational mortality of *Y. malinellus*. The impact of the parasitoids in relation to the total generational mortality of *Y. malinellus* was 19.0% in 1993, 13.1% in 1994, and 14.4% in 1995. Life tables also indicated that the population dynamics of the AEM is significantly influenced by the failure or attainment of AEM females to realise their potential fertility.

20-240

EVALUATION OF TWO PARASITIDS (HYM: BRACONIDAE) FOR THE CONTROL OF *APHIS GOSSYPYII* GLOV. AND *MYZUS PERSICAE* SULZ. (HOM.: APHIDIDAE) ON PEPPER

R. Torres del Castillo, M. Hernández García, L. Rumeu Ucelay, E. Hernández Suárez, F. Pérez Padrón, A. Carnero Hernández.

Departamento de Protección Vegetal, Instituto Canario de Investigaciones Agrarias, La Laguna, Tenerife. Islas Canarias, España.

Some trials were conducted on a pepper protected crop in order to evaluate the efficacy of *Aphidius colemani* and *Lysiphlebus testaceipes* as biological control agents on *Aphis gossypii* and *Myzus persicae* populations.

These parasitoids appear frequently in this crop and showed different host preferences and parasitization rates.

Aphidius colemani showed no preference between *Aphis gossypii* and *Myzus persicae*, and a good control on both aphids was observed.

Lysiphlebus testaceipes showed a preference only for *Myzus persicae*.

20-239

GEOGRAPHIC DISTRIBUTION OF PARASITIDS OF THE CARIBBEAN FRUIT FLY, *ANASTREPHA SUSPENS*A, IN FLORIDA
A. Eitam, J. Sivinski¹, T.C. Holler²

Department of Entomology and Nematology, University of Florida, Gainesville, FL, USA - 1 Insect Attractants, Behavior, and Basic Biology Research Laboratory, USDA-ARS, Gainesville, FL, USA - 2 USDA-APHIS, Gainesville, FL, USA

A survey was performed to determine the geographic distribution of braconid larval-pupal parasitoids of the Caribbean fruit fly. Host fruit (loquat, Surinam cherry, Cattley guava and common guava) were collected throughout central and south Florida. Fly larvae pupated in moist vermiculite, and emerging parasitoids were identified.

Diachasmimorpha longicaudata was limited to south Florida, reaching higher latitudes along the Atlantic coast. *Doryctobracon areolatus* was the dominant species in the majority of interior locations, its numbers decreasing toward the northern limit of host distribution. It was uncommon along the western coast of the peninsula, and absent along the eastern coast and the southern edge of Lake Okeechobee. Its absence on the southeast coast, where it was originally released and established, suggests that a process of displacement has occurred. The ranges of *D. longicaudata* and *D. areolatus* overlap only within a limited area, and only at one interior location were both common. *Uteetes anastrephae* was widespread, with the largest numbers being recovered from the southeast and southwest coasts, and along the southern edge of Lake Okeechobee. The different distribution patterns of the three species stress the importance of selecting biocontrol agents that are adapted to the environmental conditions of the target release area.

20-241

INTERACTIONS BETWEEN A TACHINID PARASITOID AND A GRANULOSIS VIRUS OF THE WESTERN GRAPELEAF SKELETONIZER

D. M. Stark, A.H. Purcell, N.J. Mills

Department of Environmental Science, Policy and Management, University of California at Berkeley, California, USA

Interactions between the tachinid parasitoid, *Ametadoria misella*, and the granulosis virus (GV) of the western grapeleaf skeletonizer, *Harrisina brillians*, were investigated.

In a field study, the ovipositional preference of *A. misella* for healthy or HbGV infected *H. brillians* at 3rd or 4th instar was studied to investigate the degree of interspecific competition between the natural enemies. Treatments were significantly different as determined by ANOVA ($F_{2,6}=5.97$, $p=0.04$). Comparison of individual means by pooled t-test using Bonferroni's adjustment revealed that *A. misella* oviposited, as determined by dissection, 6 times more often ($t_4=5.98$, $p<0.01$) in 4th instar *H. brillians* larvae (mean= $51\%\pm 10\%$ SD) than in 3rd instar hosts ($8\%\pm 7\%$); and 3 times more often ($t_4=2.235$, $p=0.08$) in healthy *H. brillians* larvae ($51\%\pm 10\%$) than in symptomatic HbGV infected larvae ($16\%\pm 25\%$). Additionally, a lower proportion ($F_{1,2}=5.53$, $p=0.14$), although not significantly different, of field collected *H. brillians* pupae parasitized by *A. misella* tested positive for HbGV by ELISA than nonparasitized pupae; and the mean concentration of virus, estimated by ELISA absorbance₄₀₅, in parasitized *H. brillians* pupae (0.76 ± 0.39) was significantly lower ($t_{64}=3.616$, $p<0.01$) than in nonparasitized pupae (1.27 ± 0.45). These results suggest a mechanism of stage-specific host partitioning by natural enemies which reduces interspecific competition for hosts.

The potential of *A. misella* to transmit HbGV to healthy *H. brillians* after emerging from virus infected hosts was investigated. HbGV was not detected by ELISA or bioassay in whole insect or meconium homogenates of *A. misella* emerging from HbGV-infected *H. brillians*.

20-242

ENZYMATIC ANALYSIS OF *APANTELES GLOMERATUS* (HYMENOPTERA: BRACONIDAE)

L. Oliveira*, V. Vieira* & A. Garcia**

*Departamento de Biologia, Universidade dos Açores, Ponta Delgada, Portugal

**C/ Dr. J. J. Domínguez nº5,6, 46011 Valencia, España

Apanteles glomeratus (Hymenoptera: Braconidae) is a parasitoid of *Pieris brassicae* (Lepidoptera: Pieridae) larvae in Azores Islands. This specie was characterised biochemically to improve the systematic basis of this genus. Seven enzyme systems studied by electrophoresis were analysed as aldehyde oxidase (AO), α -glycerophosphate dehydrogenase (α -GPD), tetrazolium oxidase (TO), malate dehydrogenase (MDH), glucose-6-dehydrogenase (G6PD), malic inzyme (ME), isocitrate dehydrogenase (IDH). All systems present only one band, with two exception: the AO presented two bands and the α -GPD presented three bands which corresponded to different locus. No polymorphic bands were detected.

20-243

THE TRENDS OF DIAMONDBACK MOTH PARASITIDS ON CABAGGE IN RELATION TO DIFFERENT MIXED CROPS

Khuat Dang Long, Department of Insect Ecology Institute of Ecology & Biological Resources, National Centre for Natural Science & Technology, Nghia Do -Tu Liem Ha Noi -Viet Nam
Diamondback moth (DBM), *Plutella xylostella* (L.) Is the most important pest on cabbage in North Vietnam. The population fluctuations and abundance of the pest were investigated weekly on cabbage (*Brassica oleracea* L. . *B. gongilodes* L.) from November to March of two years 1992-1994. The investigations carried out in two localities of Red River Delta showed that of two important parasitoids reared from DBM, the pest pupae parasitized by the pupal parasitoid *Phaeogenes* sp. (Ichneumonidae) was very low (maximum 3.3%) in comparison with the sole larval parasitoid *Cotesia* (= *Apanteles*) *plutellae* Kurdj. (Braconidae) (average 30.8%).

It was found that cabbage fields adjacent to maize and rice fields often have significantly lower parasitized pest population by *C. plutellae* than those on cabbage intermixed with different crops of Solanaceae, Fabaceae groups and some other decorative flowers (Asteraceae), for the maximal proportion of parasitized pest larvae was less than 25% (average 13.1%) on cabbage grown alone compared to percentage of parasitism up to 40% (average 17.7%) on the mixed planting cabbage with different crops.

In addition, cabbage fields of both above localities often treated by some pesticides as Cartap (PADAN 95BHN), Phethoate+Enthofenprox (CIDI M) but it was observed that the peak of parasitoid populations usually occurred in the middle and towards the end of the crop.

OCCURRENCE AND USE OF ENTOMOPATHOGENIC NEMATODES IN NEW ZEALAND

T.A. Jackson, T.L. Nelson and T.J. Sadler
Environmental Pest Management, AgResearch, Canterbury Agriculture and Science Centre, Gerard St, Lincoln, New Zealand.

New Zealand has a varied nematode fauna consisting of both exotic and endemic species. The entomopathogenic rhabditids are well represented by steinernematid and heterorhabditid nematodes examples of which have been isolated from soil samples and insects. These have been characterised by morphometrics and genetic analysis (PCR/RAPD). Strains of *Steinernema feltiae* have been frequently isolated from native and semi-improved hill country grasslands, suggesting that strains of this species are endemic. *Steinernema carpocapsae* and *S. glaseri* have also been isolated, but are less common and could be of exotic origin as both species have been released into the country during biological control experiments. Heterorhabditid nematodes corresponding to *H. bacteriophora* and *H. zealandica* have also been isolated, most frequently from coastal areas. Entomopathogenic nematodes, however, are seldom isolated from improved pastures, where insect pests abound, although laboratory and field tests show their potential as control agents. Heterorhabditid nematodes have been effective against pasture scarab pests and a New Zealand strain of *S. feltiae*, showing low temperature activity, has been tested and found effective against soil dwelling hepialid larvae in winter. High production costs of entomopathogenic nematodes currently preclude their use as inundative control agents in broad scale agriculture. Heterorhabditid nematodes, however, have been registered and are used commercially for control of weevil pests in plant nurseries.

21-001

HETERORHABDITIS MEGIDIS POINAR ET AL.;
A BIOLOGICAL CONTROL AGENT OF FOREST INSECTS AND A CARRIER OF ANTIFUNGAL AGENTS.
J.M. Webster¹, G. Chen¹, J.E. Saunders².
Centre for Pest Management, Simon Fraser University, Burnaby, Vancouver, Canada - 1. Ontario Forest Research Institute, Sault Ste Marie, Ontario, Canada - 2.
Heterorhabditis spp. and their symbiotic bacteria, *Photorhabdus luminescens* (Thomas and Poinar) Boemare et al., have been shown to be virulent against certain forest coleoptera, diptera, lepidoptera and hymenoptera, and to have potent fungicidal capabilities. In laboratory experiments *H.megidis* Poinar et al., caused a variable mortality among forest insects, namely 27% in *Contarinia oregonensis* (Foote), 56% in *Strobilomyia appalachensis* Michelsen, 100% in *Choristoneura fumiferana* Clemens, 100% in *Diprion similis* (Hartig) and 30% in *Otiorhynchus ovatus* L. The antibiotic, 3, 5 - dihydroxy - 4 - isopropylstilbene produced by *P.luminescens* has strong fungicidal activity with minimum inhibitory concentrations ranging from 12 µg/ml against *Cryptococcus neoformans* and *Botrytis cinerea* to 25µg/ml against *Aspergillus flavus*. Exo-chitinase and endo-chitinase also is produced by *P.luminescens* and, as well as being fungicidal, they may help the nematodes to exit the insect cadavre by softening the insect cuticle.

21-003

THE ROLE OF MERMITHID NEMATODES IN THE OUTBREAK DYNAMICS OF WINGLESS GRASSHOPPER, *PHAULACRIDUM VITTATUM* (SJÖSTEDT), IN AUSTRALIA

Graeme L. Baker
Biological and Chemical Research Institute, NSW Agriculture, P.M.B. 10, Rydalmere, N.S.W 2116, Australia

In the tablelands of south eastern Australia, small scale, chronic infestations of wingless grasshopper persist throughout the recessionary phase of the outbreak cycle in habitats unfavourable for mermithid nematodes (hot-spots), typically steep terrain with low soil moisture. Ironically, reliable host availability at hot-spots ensures the persistence of a reserve, albeit at a low level, of mermithid nematodes during the recessionary phase. The population surplus produced at hot-spots seasonally disperses to adjacent moist habitats (primary invasion areas) where, under average seasonal rainfall conditions, they are decimated by abundant mermithid nematode populations. Under drought conditions there is curtailment of activity by mermithid nematodes which results in (a) high host survival in hot-spots (b) an exceptionally large host population surplus which invades and breeds successfully in primary invasion areas and (c) the production of a high proportion of long-winged morphs at hot-spots, a consequence of high density, which disperse widely to infest grasslands made favourable for habitation by the drought (secondary invasion areas). The lack of biological control agents in secondary invasion areas results in unrestrained increase in wingless grasshopper populations relatively independent of seasonal rainfall conditions. This population growth consolidates infestations giving rise to regional outbreaks. Outbreak collapse occurs sequentially in the different habitats. In hot-spots and primary invasion areas collapse follows immediately after the return of average seasonal rainfall and consequent renewal of nematode activity. In the more extensive secondary invasion areas there is a delay of 1-2 seasons during which nematode populations establish and increase to ultimately cause localised host extinction.

21-004

HIGH TEMPERATURE STEINERNEMATIDS: CAN THEY BE USED IN PEST MANAGEMENT

N. G. M. Hague, S.A. Elawad

Department of Agriculture, The University of Reading, Reading, UK

A new species of *Steinernema* has been recovered from soil in an alfalfa field in the Sultanate of Oman where bollworms, particularly *Helicoverpa armigera*, are the main insect pests. The new species is taxonomically distinct from *S. riobravus* which was recovered from prepupae and pupae of *H. zea* and *Spodoptera frugiperda* in Texas, USA. The thermal niche breadth for infection and establishment of the two species is similar and both species will reproduce in *Galleria mellonella* between 25 and 25°C. The LT₅₀ and LC₅₀ of the two species are very similar.

Various bollworm species are the principal targets for these "high temperature" steinernematids. The paper discusses the problems of introducing new species of entomopathogenic nematode into pest management programmes.

21-006

RESEARCH ON ENTOMOPATHOGENIC *STEINERNEMA* AND *HETERORHABDITIS* IN CHINA

R. C. Han, L. Y. Li

Guangdong Entomological Institute, Guangzhou 510260, China

Steinernema and *Heterorhabditis* nematodes have been widely used for the control of insect pests as biocontrol agents in soil, cryptic and aquatic habitats, and on foliage because of their wide range of insect hosts, their ability to search for and kill hosts rapidly, ease of mass rearing and environmental safety.

In China, since the 1950's, especially the late 1970's, various species or strains of *Steinernema* and *Heterorhabditis* have been introduced from Czechoslovakia, Australia, the United States and other parts of the world, and isolated from soil or/and natural insect hosts. The current status of entomopathogenic nematode research in China was summarized as follows.

Collection and identification of *Steinernema* and *Heterorhabditis*

- * Major isolates of *Steinernema* and *Heterorhabditis* in China
- * Identification

Application of *Steinernema* and *Heterorhabditis* for pest control

- * Assays on host range
- * Field development
- * Impact on non-target organisms

Symbiotic *Xenorhabdus* and *Photorhabdus* bacteria

- * Isolation and identification of *Xenorhabdus* and *Photorhabdus*
- * Recombinations of *Photorhabdus* and *Heterorhabditis* strains

Mass production of *Steinernema* and *Heterorhabditis*

- * Improved medium ingredients
- * Optimization of the culture parameters for nematode production

21-005

EFFECT OF AGE AND NEUTRAL LIPID CONTENTS ON MOBILITY AND INFECTIVITY OF *STEINERNEMA FELTIAE*

I. Vänninen

Agricultural Research Centre, Institute of Plant Protection, Jokioinen, Finland

A Finnish (SFS-22) and a Swedish (Umeå) isolate of *Steinernema feltiae* were stored for 1040 and 970 days, respectively, in moist polymer gel at 20°C and bioassayed at 1-3 months' intervals to study the effect of age and lipid contents on mobility and infectivity in a mobility test where infectives had to travel a 9 cm distance in sand cylinders to reach bait larvae (*Tenebrio molitor*), and in an infectivity test where nematodes were placed in the close vicinity of bait larvae in 5 ml sand pots. Some SFS-22 batches were transferred to 25°C after a year's storage at 20°C to obtain nematodes of similar physiological but of different chronological age. Lipid contents of infectives were measured with image analyzer after staining lipids with Oil-Red-O.

Due to clean storage conditions mortality of both isolates reached only 55-60 % by the end of the experiment. Both isolates were infective till the end, despite that about 90 % of infectives were devoid of lipids. Mobility decreased more quickly than infectivity. In sand cylinders, the mortality of baits and number of nematodes reaching the bait larvae dropped to a low level after the proportion of infectives devoid of lipids began to increase but in the infectivity test these parameters remained on the original level for 900 days. In time, infectivity and mobility fluctuated in close concordance with each other for SFS-22, but seemed not to be as tightly linked for the Umeå isolate. There were distinct differences in the pattern of activity of the two isolates in relation to time and depletion of lipid resources. Storage temperature affected the performance of aging nematodes as the mobility and infectivity of SFS-22 from 25 °C was always less than infectivity of SFS-22 from 20°C with similar lipid contents but of greater chronological age.

21-007

SALINITY EFFECTS ON THE INFECTIVITY AND HEAT TOLERANCE OF THE ENTOMOPATHOGENIC NEMATODE *HETERORHABDITIS* SPP.

C.T. Griffin, M.F. Finnegan & M.J. Downes

Department of Biology, St. Patrick's College, Maynooth, Co. Kildare, Ireland.

Entomopathogenic nematodes of the genus *Heterorhabditis* are frequently found in sandy coastal soils, and it has been suggested that the genus evolved from marine ancestors. We compared the performance of *Heterorhabditis* infective juveniles in sea water and distilled water. Isolates of each of the three taxonomic types found in Europe were tested: *H. bacteriophora*, and *Heterorhabditis* sp. of the North-West European and Irish Groups. Sea water protected the infective juveniles against the lethal effects of high temperatures, but the infectivity of all types for *Galleria mellonella* larvae was reduced in sand moistened with sea-water compared to that in sand moistened with distilled water. The basis for these effects, and differences between types, will be discussed.

21-008

SOIL - INHABITING PESTS AS THE HOSTS FOR THE ENTOMOPATHOGENIC NEMATODES

Magdalena Jaworska

Department of Agricultural Environment Protection, Academy of Agricultural, Mickiewicz Ave., 21, 31-120 Cracow, Poland

Entomopathogenic nematodes in the families *Steinernematidae* and *Heterorhabditidae* are widely regarded as being excellent biological control agents for a number of insect pests in soil. The research on natural enemies of the apple sawfly - *Hoplocampa testudinea* Klug., a serious pest of sub - carpathian orchards, undertaken 20 years ago enable to isolate, for the first time in Poland, a newly described genus *Heterorhabditis*. Semi - field trials showed a high effectiveness of the nematodes, applied into soil, against the apple sawfly. In micro-plot experiments nematodes applied in high doses prophylactically through watering young seedlings of cauliflower, onion and carrot plants, protected them from the relevant fly pests as efficiently as chemical treatments. No effect of entomopathogenic nematodes on the mortality of *Ichneumonidae* inside cocoons of apple sawfly larvae or closed in *Delia* pupariums was found.

The recent studies revealed that other groups of soil - inhabiting pests were also suppressed by entomopathogenic nematodes, thus biological pest control on vegetable crops could be extended into other agrophagous invertebrates such as terrestrial isopods (*Porcelio scaber* Latr.) millipedes (*Blaniulus guttulatus*) and even slugs (*Deroceras*, *Arion*). However infective juvenile production of nematodes was not completed in every case.

21-010

SPECIES IDENTIFICATION OF THE ENTOMOPATHOGENIC NEMATODE *HETERORHABDITIS* BY MOLECULAR AND CROSS-BREEDING TECHNIQUES

I. Dix, A. M. Burnell

Department of Biology, St Patrick's College, Maynooth Co. Kildare, Ireland

Heterorhabditis is an important agent for the biological control of insect pests in the soil. The complex life-cycle of *Heterorhabditis* nematodes makes them less amenable for introducing beneficial traits by means of interstrain crosses, which would make them more effective in field application. First generation *Heterorhabditis* hermaphrodite females give rise to a second generation which contains amphimictic females and males and hermaphrodite females. The nutrient status of the environment in which larval development occur plays an important role in determining the ratio of these progeny types.

However in carefully controlled experiments, the amphimictic females can be selected and used for genetical crosses. By these crosses new traits could be introduced and also biological species could be identified among the large number of isolates collected in recent years.

Details of these crosses and comparison of species identification by crosses vs. PCR amplification will be presented. Our present understanding of the life-cycle, which is important in utilising the genetic approach to strain improvement, will also be discussed.

21-009

GENETIC IMPROVEMENT OF HEAT TOLERANCE IN *HETERORHABDITIS BACTERIOPHORA* POINAR.

D. Shapiro¹, I. Glazer¹, and D. Segal²

¹ Department of Nematology, Agricultural Research Organization The Volcani Center, Bet Dagan 50250, Israel

² Department of Molecular Microbiology and Biotechnology, Tel Aviv University, Tel Aviv 69978, Israel

Exposure to environmental extremes such as high temperatures may hinder the biological control efficacy of entomopathogenic nematodes. Therefore research has been initiated to find or develop superior nematodes through genetic improvement. In the present study, a heat tolerance trait was transferred from one strain of the entomopathogenic nematode *Heterorhabditis bacteriophora* Poinar to another. The trait was transferred from the heat tolerant IS5 strain to the commercial HP88 strain through controlled crosses. The hybrid nature of the progeny was verified using a marker mutant of the HP88 strain (*Hp-dpy-2*). Heat tolerance in the hybrid progeny was similar to the IS5 strain and significantly greater than the HP88 strain. The virulence at high temperatures (32°C) of the IS5 and hybrid nematodes was greater than HP88 nematodes. Similar to the IS5 strain, the hybrids displayed sensitivity to cold. No differences were detected in reproductive potential among the strains. This study demonstrates the promise of using hybridization to genetically improve entomopathogenic nematodes, and illustrates the advantage of using marker mutations in this endeavor.

21-011

STUDIES ON THE GENUS *HETERORHABDITIS* POINAR, 1975 IN ARGENTINA.

M. Agüera de Doucet. Centro de Zoología Aplicada Univ. Nac. de Córdoba. CC 122. 5000 Córdoba, Argentina.

The genus *Heterorhabditis* appears as the most extensive distribution in Argentina. It was recovered in a large diversity of milieu including near Atlantic and Andes mountains areas and the central region of the country. It was frequently founded in cultivated and natural areas. The work carried out in the Laboratorio de Nematología, Centro de Zoología Aplicada, comprised several subjects.

A) Survey and detection: soil and insects samples arising from different localities of the country were analyzed. At present all the isolates belong to the species *H. bacteriophora* Poinar, 1975. This shows the plasticity and variability that characterizes the species.

B) Isolates characterization: it is realized on the basis of the analysis of several characters. 1) Morphologiques. Taking into account the stages commonly considered no significant differences were observed among isolates. 2) Morfométriques. The greatest variability was observed in hermaphrodites and in females; the minor in males and infective larvae. According to the stage the degree of variability is different. That variability appears closely associated with the conditions of milieu (environment and host). 3) Life cycle. It was observed a succession of three hermaphrodite generations and an only one amphimictic, this one was overlapped to the second hermaphrodite. The disponibility in food influences the modality and the time parasitaire. Generally, the bigger the infection, the shorter the cycle and the faster the production of new infectives. 4) Patterns Distribution in soil. Horizontal and vertical patterns in infective larvae were aggregative. Concerning the layer preference the larvae were often found between 10-30 cm. in depth. 5) Specificity and Infectivity. Specificity appears mainly conditioned by ecological factors. Isolates showed different aggressive degrees in relation to determined host.

Up to now, the data contribute to the knowledge of *H. bacteriophora* and they are orientated to the selection of useful isolates for the control against harmful insects.

21-012

ISSUES AND CONCERNS REGARDING ENTOMOGENOUS NEMATODES

G.O. Poinar, Jr.

Department of Entomology, Oregon State University,
Corvallis, OR 97331

The field of entomogenous nematodes has developed rapidly during the past two decades. The great majority of this activity has been due to studies on the entomopathogenic nematodes *Steinernema* and *Heterorhabditis*. Aside from the many advances made in this complex area, there is now a need to address the following basic concerns.

1. What type of information should be used for the basis of a species concept: morphological, genetic or molecular?
2. If morphological, which characters are the most stable in light of geographical variation? If molecular, which sequences on which genes will be the most useful for species differentiation and which should be used to detect intra-specific variation?
3. How important is species and strain diversity in relation to host selection?
4. What are the geographical ranges of species of *Steinernema* and *Heterorhabditis*? How many of these species are inter-continental? Are some described species simply strains of other described species? How rapidly does speciation occur in these genera?
5. What are the natural means of distribution of species in these genera and how does this relate to speciation? How important are abiotic factors in the development of new species?

Regarding entomogenic nematodes in general, the fossil record can tell us about the past distributions of nematodes and their hosts, the antiquity of insect parasitism by nematodes and explain present day host preference phenomena.

21-014

THE INDIRECT EFFECT OF PLANT HOST ON THE SUSCEPTIBILITY OF SITONA LINEATUS L. TO ENTOMOPATHOGENIC NEMATODES

D. Ropek and M. Jaworska

Department of Agricultural Environment Protection, Academy of Agricultural,
Mickiewicz Ave., 21, 31-120 Cracow, Poland

The pea and bean weevil *Sitona lineatus* (Col., Curculionidae) is an important pest of leguminous crops in many parts of the world. In Poland, the pest status of *S. lineatus* has increased within the last years. Adult weevils overwinter in perennial legumes such as lucerne and clovers. After migration to annual legume crops in spring, weevils mate and lay eggs. Larvae feed on the nitrogen fixing root nodules. Previous attempts using entomopathogenic nematodes (EN) for microbial control of this insect have been directed against young instars from clover stands and showed that these weevils are susceptible to EN. Field trials showed that *S. lineatus* were most abundant in early spring period on plots with various cultivars of pea. In May in egg laying period, bean cultivars became more attractive. Laboratory studies on the preference for annual legumes by pea weevils showed that activity and natural mortality of *S. lineatus* adults may be connected with host plant preference which influences feeding activity, average body weight and susceptibility to EN. Larvae of *S. lineatus* were shown to be the most susceptible stage for infection by EN, especially those feeding on peas. The nematodes were able to reproduce effectively in all cadavers, but juveniles of EN emerged in greater quantities from *S. lineatus* larvae from beans than with those from peas. The greatest number of infective juveniles was obtained from *S. lineatus* larvae from late field bean. Adults of the new summer generation of *S. lineatus* from pods reached higher mortality rates than those from beans. These results indicate the importance of including different host plants in testing nematodes against insect species.

21-013

UTILIZATION OF *CULICOIDES VARIIPENNIS* LARVAE BY THE MERMITHID NEMATODE *HELEIDOMERMIS MAGNAPAPULA*, AND INTERACTIONS WITH IRIDESCENT VIRUS INFECTION

B. A. Mullens, K. A. Lühring, R. K. Velten

Department of Entomology, University of California, Riverside,
California 92521 USA

Aquatic larvae of the blood-feeding midge and bluetongue virus vector *Culicoides variipennis sonorensis* are parasitized by a mermithid nematode, *Heleidomermis magnapapula*. Young host larvae (L1 & L2) are preferred for parasitism in the laboratory and field, leading to successful development and emergence from late instar larvae (L4). Distribution of adult nematodes in the field allows optimal contact with young hosts. In the laboratory, preparasites take longer to enter older hosts, and older larvae are more likely to encapsulate parasites or to eat the preparasites before they have an opportunity to penetrate. Still, parasitism of late instars probably is critical for nematode dispersal among spatially or temporally isolated developmental sites (e.g. dairy wastewater ponds) via parasitized adult midges.

Host larvae in one dairy wastewater pond were concurrently infected with iridescent virus; virus infection reached 30% or more among second instar hosts. Infected larvae in the field were essentially all parasitized by *H. magnapapula*. Exposure of naive host larvae to virus in the laboratory resulted in <2% infection, while exposure in the presence of mermithid preparasites caused nearly 100% virus infection, probably due to virus introduction into the host hemocoel by the nematode. Virus incubation (4-5 days) is less than time required for successful parasite maturation (12-15 days), leading to death of both mermithid and host. This results in an interesting scenario, in which the superior biological control agent, *H. magnapapula*, suffers, while an inefficient pathogen benefits. The evolutionary implications of this relationship will be discussed.

21-015

THE AREA OF DISCOVERY AND HOST SEARCHING STRATEGY OF AN ENTOMOPHAGOUS NEMATODE *HETERORHABDITIS BACTERIOPHORA* IN SOIL COLUMNS.

Varsha Baweja, S.S. Sehgal

Department of Zoology, University of Delhi, Delhi-7, India

The host searching behaviour of infective juveniles (IJs) of *Heterorhabditis bacteriophora* was ascertained in terms of their area of discovery and vertical migration in the soil columns in a laboratory bioassay. In assessing the potential of *H. bacteriophora* as a promising biological control agent, it is a prerequisite to understand the searching capacity of the IJs in their microniche i.e. soil. The area of discovery of IJs of *H. bacteriophora* was observed to be affected by the density of the host larvae in the soil column and it is calculated to be 0.176. Vertically the IJs migrated down ca. 15cm in the soil-column and were able to parasitize successfully 66.66% of the *Spodoptera litura* (Lepidoptera: Noctuidae) larvae, the target host, within two days interval. The searching efficiency with respect to various other parameters is also discussed.

21-016

Foliage Protection And Mortality Reduction In Prestressed Hardwood Forests During A Massive Outbreak Of Gypsy Moth (*Lymantria Dispar* L.)

H. Gossenauer-Marohn, J. Gonschorrek, R. Riebeling
Hessian agency of forest management planning, forest ecology and forest research, Gießen/Hann.-Münden, Germany

From 1992 - 1995 the deciduous hardwood forests in the plains and hillbelts of Germany were confronted with the heaviest outbreak of Gypsy Moth in the recent forest history. In 1994, the year of culmination, a total amount of 190000 acres was infested.

In Hesse, the aerial counter treatments were used to perform an experimental programme to optimize the foliage protection and to monitor reactions of unprotected stands.

First results of these long-term field trials are:

1. The pattern of Gypsy Moth distribution was disjunctive, often due to wind drift among first and second instar larvae.
The egg masses were concentrated in heights of more than 4 meters above ground. In areas with high population densities the ground vegetation had been totally destroyed subsequent to crown defoliation. Only *Prunus serotina*, *Impatiens noli-tangere*, *Deschampsia flexuosa* and *Urtica dioica* were resistant.
2. Up to an egg mass density of 10 per tree *Bacillus thuringiensis* (Btk) - applications with FORAY 48B^R (4l/ha; 50,4 x 10⁹ IU) and DIPEL ES^R (2l/ha; 33,4 x 10⁹ IU) showed good efficacy compared to the one of DIMILIN^R (Diflubenzuron 150 g/ha).
The stand density and vertical structure had an important influence: stands with two or more layers showed minor foliage protection after Btk-applications.
3. Dimilin^R - treated areas at first sight revealed more negative ecological effects than Btk-areas. Long-lasting effects cannot be proved yet.
4. Stands with intact ground water regime showed no remarkable damage.
Total defoliation in predisposed stands reduced the radial growth of trees down to zero.
Only those trees which had been protected reached their prior growth rates.
5. The current monitoring programme will reveal further results for the management of valuable mixed natural stands in the Rhine-Main-area.

21-018

INCESTICIDAL ACTIVITY OF *BACILLUS THURINGIENSIS* SUBSP. *KURSTAKI* HD-1 AND SUBSP. *SOTTO* BIOTYPE *DENDROLIMUS* AGAINST *DENDROLIMUS PINI* (L.) (LEPIDOPTERA: LASIOCAMPIDAE)

A. Sierpińska

Department of Forest Protection, Forest Research Institute, Warsaw, Poland

The pine moth (*Dendrolimus pini* L.), a serious primary pest of Scots pine (*Pinus sylvestris* L.) in Poland, was controlled over a total area of about 200 thous. ha in 1950-95.

The increase of *B. thuringiensis* (B.t.) spraying range stimulates to a searching of B.t. strains more efficient in pests control. The insecticidal activity of B.t. subsp. *kurstaki* HD-1 and B.t. subsp. *sotto* biotype *dendrolimus* against 2nd and 5th instars larvae of the pine moth was compared. Bioassayed larvae were infected during a feeding on pine needles dipped in B.t. suspensions. Mortality of larvae reared at 25°C, 70-75 % RH and D:L - 16:8 was checked and LT₅₀ was calculated. For 5th instar larvae the number of frass was counted. Experiments showed that B.t. subsp. *sotto* biotype *dendrolimus* seems to be more promising in the control of *D. pini* than B.t. subsp. *kurstaki* HD-1.

21-017

MICROBIAL CONTROL OF GYPSY MOTH DURING THE GRADATION 1992 - 1994 IN GERMANY: RESULTS OF FIELD TRIALS USING *BACILLUS THURINGIENSIS* AND NUCLEAR POLYHEDROSIS VIRUS

J. Huber, R.G. Kleespies, G.-A. Langenbruch

Institute for Biological Control, BBA, Darmstadt, Germany

The last mass outbreak of gypsy moth in Hesse, Germany, was used to compare different concentrations and also mixtures of *Bacillus thuringiensis* (B.t.) and Nuclear Polyhedrosis Virus (NPV). The results of these field trials, using aerial and ground application, can be summarized as follows:

- 1) Application rates of B.t., as approved by the registration authorities and used by the forest service up to 1994 (1.5·10¹⁰ IU/ha), were too low to get adequate control of gypsy moth.
- 2) Since 1994, the registration of B.t. preparations covers application rates similar to the rates used in North America (1·10¹¹ IU/ha). Use of these new, higher rates lead to excellent control of first instar larvae of gypsy moth and good protection against defoliation.
- 3) Egg mass treatment from the ground with NPV resulted in a high virus infestation of the gypsy moth population, but was not able to prevent defoliation.
- 4) Two treatments with a high concentration of NPV (1.3·10¹² Polyhedra / ha) gave an acceptable level of protection against defoliation and an excellent reduction of the gypsy moth population.
- 5) Combining B.t. and NPV was particularly promising (and economically attractive) when both pathogens were applied at relatively low dosage. A mixture of 1/10 of the normal concentration of B.t. and NPV gave similar larval reduction and foliage protection as the full B.t. dose. The virus was established in the population and, thus, could give long term control.

In the following year (1995), at most locations, no further field trials were possible as the gypsy moth populations collapsed completely due to parasitoids and/or virus.

21-019

INFLUENCE OF EATING BY *THAUMETOPOEA PITYOCAMPA* SCHIFF. (LEPIDOPTERA: THAUMETOPOEIDAE) IN THE PROCESS OF THE GROWTH OF *PINUS BRUTIA* TEN.

N.D.Avtzis, G. Chatziphilippidis¹

Laboratory of Entomology, Department of Forestry, Technological Education Institute (TEI), 66100 Drama, Greece - 1 Forest Research Institute, 57006 Vasilika - Thessaloniki, Greece.

The main reasons for this experiment were the relatively large area the forests of *Pinus brutia* Ten. which exists in Greece, and the intensive attack from the needle-eating insect *Thaumetopoea pityocampa* Schiff. The aim of this treatment was the investigation of the effects that three successive total defoliations had on the growth of young trees. The field experiment was established in the estate of the Forest Research Institute and included:

- a) Total defoliations during the follow periods:
- 1986-87, 1987-88, 1988-89 (attack 86)
- 1987-88, 1988-89, 1989-90 (attack 87), and
- b) Measurements of height and diameter of the trees at every two months.

The results are the following:

- 1) No deaths (partially or totally) were observed, either to the control (full protection against any defoliation), or even to the total defoliation regimes applied.
- 2) Heights and perimeters of the defoliating trees were lower than those of the control (49,1-59,5%).
- 3) For two years after the end of the last defoliation the trees grew still slower than those at the control.

21-020

MICROBIAL CONTROL OF THE PINE PROCESSIONARY CATERPILLAR, *THAUMETOPOEA PITYOCAMPA* DEN. & SCHIFF., IN ITALY (LEPIDOPTERA: THAUMETOPOEIDAE)

A. Battisti¹, S. Longo¹, R. Tiberi², O. Triggiani³

Istituto di Entomologia agraria, Università di Padova, Italy - 1 Istituto di Entomologia agraria, Università di Catania, Italy - 2 Istituto di Patologia e Zoologia Forestale e Agraria, Università di Firenze, Italy - 3 Istituto di Entomologia agraria, Università di Bari, Italy.

The Pine Processionary Caterpillar *Thaumetopoea pityocampa* is the most important defoliator of both native and introduced pines all over Italy. In particular it is the key species in young plantations and on ornamental trees. The life cycle is characterized by two striking features, as the gregariousness of the larvae and the prolonged diapause as a pupa in the soil, resulting in a high degree of adaptability to various environmental and climatic conditions.

A number of microbial antagonists have been isolated from larvae and pupae in the last 30 years. Some of them have been also used in experiments of biological control, providing encouraging results. However, only *Bacillus thuringiensis* has passed the experimental screening and it is now available for routine treatments, even if its application from the air is subjected to a strict limitation by national rules.

The high variability in effectiveness observed in the field after a single application of *B.t.* (20-85% of mortality) is related to a great variability in some population parameters of *Th. pityocampa*. The emergence period of adults varies from July (Alps) to October (South) and its duration is related to the spreading of the cohorts (individuals with life cycle of different length) over time. In addition, the embryonic development takes from 20 to 45 days, depending strictly on the temperatures recorded in the egg masses. As a result, the most vulnerable larval instars (L1 and L2) are never thoroughly reached by one application only, as the persistence of the bacteria on the needles is usually limited. Two applications are requested to control the pest in stands where the egg hatching occurs over more than one month.

21-022

THE FUTURE OF *BACILLUS THURINGIENSIS* IN FORESTRY.

John Sanders

ABBOTT LABORATORIES - CAPD, UK

There are four commercially available endotoxin producing strains of *Bacillus thuringiensis* (Bt). Bt sps *kurstaki*, Bt sps *aizawai*, Bt sps *tenebriones*, and Bt sps *israelensis*.

The most widely used strain is Bt *kurstaki* (Btk.), which is employed for the control of forest defoliating lepidopteran larvae. Over 90% of North American forests that are treated for lepidopteran defoliators now employ Btk. Whereas in Europe only 30% of the treatment are now made with it, offering a considerable growth potential, as do other parts of the world whose forests, similarly affected by lepidopteran larvae. Bt *tenebriones* (Btt), shows promise for control of many defoliating chrysomelidae. Good results being obtained from a wide number of species. Interestingly, adult beetles from other defoliating coleopteran families have also succumbed after feeding on treated leaves.

Of the other two subspecies, Bt *aizawai* (Bta) could perhaps be used to treat lepidopteran larvae, if its economics were more favourable. Bt *israelensis* (Bti), on the other hand has yet to find a target.

21-021

USE OF *BACILLUS THURINGIENSIS* AND *BACULOVIRUS* FOR THE NUN MOTH *LYMANTRIA MONACHA* (LEPIDOPTERA: LYMANTRIDAE) CONTROL

B. Glowacka

Forest Protection Department, Forest Research Institute, Warsaw, Poland

The nun moth is an insect occurring in outbreaks in coniferous stands in Europe. Due to the high population density of pests and the risk of a complete damage to stands, control treatments are to be carried out every several years.

Laboratory studies on the use of pathogenic microorganisms as bioregulators of the nun moth numbers showed that the larvae are sensitive to *Bacillus thuringiensis* and nuclear polyhedrosis virus.

The results of control treatments with different *B.t.* commercial products varied over years. At present ULV formulations used at the doses of 3-4 l/ha are efficiently applied in forest protection in Poland. In 1994 Foray 48B was used in an area of 150 thousand ha causing high mortality and collapse of the nun moth outbreak.

Disease of the nun moth larvae caused by LmMNPV was one of bioregulators of the pest in Europe in the past when the nun moth attacked mainly the Norway spruce stands. During the last two outbreaks (1978-1984 and 1992-1994) in Poland the nun moth occurred generally on the Scots pine and no viral epizooties were observed. The nun moth control treatments at pine stands with the polyhedra of LmMNPV showed a low infectivity of the virus which means that it can not be considered as a pathogen useful in the nun moth control programmes at Scots pine stands.

21-023

FLUORESCENT WHITENING AGENTS AS SUNLIGHT PROTECTANTS AND ACTIVITY ENHANCERS OF INSECT PATHOGENIC VIRUSES

Martin Shapiro, USDA-ARS, Insect Biocontrol Laboratory Beltsville, MD, USA

Fluorescent whitening agents (FWA's) are commonly used in detergents and in paper manufacturing to enhance whiteness in clothes and paper. These chemicals have also been shown to be excellent sunlight protectants for viruses, nematodes, and fungi. In addition, they act as viral activity "enhancers" in several host-virus systems. The discovery, effects, and properties of these chemicals will be discussed in terms of both virulence and host spectrum. In addition, the stability of the FWA's and relationship between structure and function will be discussed.

21-024

RECENT ADVANCES IN FORMULATING BT AND OTHER MICROBIALS FOR INSECT CONTROL

M.R. McGuire

USDA-ARS-NCAUR, Bioactive Agents Research Unit, Peoria, IL USA

Formulation of *Bacillus thuringiensis* (Bt), viruses, fungi, and nematodes each present interesting and unusual challenges. Some of these agents are not palatable to insects and sunlight and rainfall contribute to the loss of insecticidal activity in different ways. Formulation may alleviate these problems. Matrix-forming materials derived from cornstarch, corn flour, wheat gluten, casein or lignin extend the residual activity of Bt significantly better than conventional formulations. These materials can be used in granular or sprayable formulations and are easily modified to fit the needs of a particular pest-crop situation. Granular formulations of Bt have been extensively tested against the European corn borer in field corn. In rainy weather, Bt formulated in cornstarch stays longer in the whorl of the plant than Bt formulated conventionally. Laboratory tests demonstrated that neonate corn borers preferred to feed on granules made from pregelatinized corn flour even in the presence of fresh plant material. Sprayable formulations have been tested on cabbage against diamondback moth infestations and residual activity measurements have been conducted against cabbage looper larvae. In both cases, matrix forming materials protected Bt from both rainfall and sunlight better than a commercial formulation. Preliminary work conducted with viruses suggests that not all the matrix-forming ingredients perform the same with respect to protection of viral activity but that some may be suitable. Formulation of fungi and nematodes present far different challenges than viruses or bacteria in that humidity and free moisture play an essential role in survival of the infectious particle until contact with a suitable host. Work is currently in progress with these two organisms.

21-026

Insecticidal activity of isolates of *Bacillus thuringiensis* on larvae and adults of *Bactrocera oleae* Gmelin (Dipt. Tephritidae)

S. Gash, D. Ellar

Dept. of Biochem. Univ. Cambridge, England

S. Aptosoglou, M. Arsenakis, A. Sivropoulou, E. Vasara, S. Koliais
Dept. of Genetics Univ. Thessaloniki, Greece

T. M. Alberola, Y. Bel, F. Granero, M. J. Martínez-Sebastián, J.Ferré
Dept. de Genetica Univ. Valencia, Spain

G. Delrio, S. Rubino, A. Satta, G. Scarpellini, R. Prota
Ist. Entomol. e Ist. di Microb. e Virol. Univ. Sassari, Italy.

Several hundreds of *Bacillus thuringiensis* isolates have been obtained from the proximity of olive groves and in olive presses in several areas of Greece, Sardinia (Italy) and Spain. Most of the isolates have been bioassayed for toxicity against *Bactrocera oleae* (Gmel.) (Dipt. Tephritidae) (larvae and adults). The levels of biotoxicity detected differ significantly amongst the isolates. The toxicity against larval stage of *B. oleae* does not always correspond to the biotoxicity against the adults. Gene analysis of the most toxic strains for most of the known toxin genes has revealed that several isolates are not harboring any of the known delta-toxin genes; these strains therefore could contain novel toxin genes.

21-025

USE OF MICROSPORIDIA FOR MANAGEMENT OF MOSQUITOES

J.J. BECNEL

U. S. Department of Agriculture, Agriculture Research Service, Medical and Veterinary Entomology Research Laboratory, Gainesville, Florida USA.

Tremendous progress has been made in recent years to resolve the complex relationships between pathogenic microsporidia and their mosquito hosts. Recent attention has focused on species of heterosporous (polymorphic) microsporidia belonging to the genera *Amblyospora* and *Edhazardia*. Heterosporous microsporidia are characterized by intricate life cycles involving multiple spore types responsible for horizontal (per os) and vertical (transovarial) transmission. These microsporidia affect two generations of the mosquito host, some require an obligate intermediate host and they are generally very host and tissue specific. Microsporidian parasites detrimentally impact mosquito populations by 1) causing high levels of larval mortality following vertical transmission and 2) through a reduction in the overall fitness of the infected adult following horizontal transmission. This information has been used to evaluate these parasites as biocontrol agents of mosquitoes and to examine their role in preventing the transmission of disease to man and animals.

21-027

RECENT ADVANCES IN THE USE OF ENTOMO-PATHOGENIC FUNGI FOR PEST CONTROL IN FIELD CROPS

S. P. Wraight¹ and T. J. Poprawski^{1,2}

¹ USDA-ARS Biological Control of Pests Research Unit, Weslaco, TX USA

² Texas Agricultural Experiment Station, Weslaco, TX

Use of pathogenic fungi for biological control of insect pests infesting field crops has been pursued for more than a century, with only limited commercial success. Important recent advances, however, have led to a steadily increasing interest in product development, and since the beginning of this decade, a number of hyphomycete-based mycoinsecticide products have been patented and/or registered worldwide for use against a variety of insect pests. The long-term commercial potential of these new fungal products is being carefully evaluated by an agricultural community seeking softer alternatives to broad spectrum synthetic chemicals insecticides. In this presentation we discuss promising new fungus production and formulation technologies and application methods and strategies that are translating into greater and more consistent efficacy under field conditions. *Beauveria bassiana*, one of the most ubiquitous and extensively studied of the entomopathogenic fungal species, is the active agent in many of the products currently under development. The present status of development of this fungus for control of *Bemisia tabaci* (Homoptera: Aleyrodidae) and *Leptinotarsa decemlineata* (Coleoptera: Chysomelidae) is reviewed to illustrate current progress and prospects for successful incorporation of fungal agents into diverse integrated pest management systems.

21-028

FUNGAL PATHOGENS FOR INSECT CONTROL IN FRUIT TREE ORCHARD SYSTEMS

Gary J. Puterka

USDA-ARS, Appalachian Fruit Research Station, Kearneysville, WV, USA

Use of fungal pathogens for control of insect pests in orchards has been a much neglected area of research. Microbial insecticides are considered to be impractical for insect pests that directly feed on the fruit because of low damage thresholds, thus, chemical insecticides have been favored. However, microbial insecticides can be a suitable alternative to chemical insecticides for controlling insect pests that do not directly feed on the fruit, but instead, feed primarily on tree leaves. Considerable amounts of chemical insecticides are used against these pests because they lower yields by reducing net photosynthesis or by indirectly damaging the fruit by insect honeydew. Herein, I review past uses of fungal entomopathogens in orchard systems and report my efforts in using fungal pathogens for controlling pear psylla, *Cacopsylla pyricola* Foerster, a serious indirect pest of pear. Based on laboratory bioassays, isolates of *Beauveria bassiana* and *Paecilomyces fumosoroseus* were chosen for field studies. Various formulations of conidia were applied at 4.9×10^{13} /hectare at different times of the season from 1993-1995 and nymphal mortalities were monitored over a 7-9 day period. Mortalities peaked 5-7 days after application and varied from 20-70% mortality, depending on the formulation and environmental conditions. Spore survival was not enhanced by formulation and spore mortalities were >70%, 24 hours after application. The potential of fungal pathogens for controlling this pear psylla will be discussed in light of these results.

21-030

RECENT ADVANCES IN FORMULATION AND APPLICATION OF FUNGAL PATHOGENS FOR CONTROL OF AFRICAN LOCUSTS

D. Stephan, G. Zimmermann

Federal Biological Research Centre for Agriculture and Forestry, Institute for Biological Control, Darmstadt, Germany

Since the massive desert locust upsurge of the late 1980s, national and international research projects were set up to develop environmentally safe locust control methods. Investigations on fungal insecticides were mainly fostered by the German GTZ-BBA project, the international LUBILOSA project and the USAID project at the Montana State University. During these studies, the fungi *Beauveria bassiana*, *Metarhizium anisopliae* and, especially, *M. flavoviride* were the most promising candidates for biocontrol of African locusts. Recently, important progress has been made in the mass production of infective fungal propagules, their formulation and their application in the field. Conidia are produced on the surface of solid or liquid media, whereas blastospores or submerged conidia are produced in liquids in fermenter systems. The LUBILOSA project developed an oil-based formulation of conidia of *M. flavoviride* for use in controlled droplet application technology at ultra-low-volume (ULV) rates. Within the GTZ-BBA project, we developed an experimental product based on spray-dried blastospores of *M. flavoviride*. These show an excellent shelf life up to two years at 5 °C and they can be suspended both in water and oil. In a comparison of different formulations in semi field trials in Mauretania, a water-based formulation (20% molasses + 80% water) of spray-dried blastospores caused a high mortality against larvae and adults of *Schistocerca gregaria* after ULV application. - The importance of efficient and stable formulations, their compatibility with standard application methods and the integration of a mycoinsecticide in a locust control strategy will be discussed.

DEVELOPMENT OF *METARHIZIUM ANISOPLIAE* FORMULATIONS WITH NEW DELIVERY SYSTEMS FOR THE CONTROL OF CRUCIFER PESTS.A.I. David-Henriet, B.J. Pye, L. Ibrahim¹, T.M. Butt².

Biological and Ecological Chemistry Dpt.- 1 & 2 Entomology and Nematology Dpt. IACR-Rothamsted, Harpenden, Herts. AL5 2JQ U.K.

Oilseed rape (OSR) is one of the most important oleaginous crops in Europe. New microbial based strategies are under development to reduce the input of chemical pesticides in this crop. Isolates of the entomogenous *Metarhizium anisopliae* have been identified which are highly pathogenic for several crucifer pests, including *Psylliodes chrysocephala*, *Lipaphis erysimi* and *Myzus persicae*, yet comparatively harmless to honey bees.

Conidia of *M. anisopliae* were formulated in different oil types (mineral, paraffin and vegetable). The best results were obtained using a paraffinic oil carrier (Shellsol T at 70%) and with either mineral oil (Ondina-El at 30%) or a vegetable oil (e.g., Sunflower oil at 30%, groundnut oil, soya oil...). Applications using these formulations resulted in up to 70% mortality of adults *Phaedon cochleriae* (using as a model to compare with *Psylliodes chrysocephala*) five days post-inoculation.

Ultra low volume application of conidia/spore formulations were applied using the APE 80, electrostatic delivery system developed at Rothamsted. Much improved deposition of inoculum was obtained in field trials with the electrostatic delivery system compared with conventional hydraulic spraying systems.

A comparison was made between conventional aqueous formulations of conidia and the oil formulated conidia. The latter consistently gave increased insect mortality over the same time period.

21-031

EFFECTS OF THE *BEAUVERIA BASSIANA*-BASED MYCOINSECTICIDE MYCOTROL® ON A PARASITOID OF *BEMISIA TABACI*W. A. Jones and T. J. Poprawski¹

USDA, ARS, Subtropical Agricultural Research Laboratory, Biological Control of Pests Research Unit, Weslaco, TX USA -1 Texas Agricultural Experiment Station, Texas A&M University, Weslaco, TX USA

Laboratory tests were conducted to determine if *Beauveria bassiana* (at 1000 spores/mm² of strain GHA) kills immature *Eretmocerus* sp. at 1, 2, 3, 9, and 13 d after parasitization. Treatments were: fungus in an aqueous carrier containing 0.02% Tween 80 surfactant, 0.02% Tween 80 solution without fungus, and water alone (control). Spore applications were made to host nymphs on excised sweet potato leaves rooted in hydroponic solution.

The results generally demonstrated that following parasitoid egg hatch, the fungus was unable to colonize parasitized host nymphs. For the 9- and 13-d-old treatments, no infection of parasitized hosts was successful. Rates of successful parasitism among hosts sprayed at day 3 were similar to those in the controls. Rates of infection at day 1 and 2 were similar to that for unparasitized host cohorts. Spores applied to the cuticle of parasitized nymphs germinated normally and penetration pegs were present. Longevities of adults surviving the 3- and 13-d-old fungus sprays were significantly lower than those surviving the Tween 80 solution, but no difference was measured for the 9 d treatment. Fecundity between mated females surviving the 13 d treatments of fungus and Tween 80 was not significantly different, producing 148.1 and 164.2 mean progeny per female, respectively.

Field tests of Mycotrol in vegetables demonstrated that application of the fungal pathogen against whiteflies is less lethal to foraging parasitoids than insecticides.

21-032

GEOGRAPHICAL AND SPATIAL DISTRIBUTIONS OF THE ENTOMOPHAGOUS AND MYCETOPHAGOUS NEMATODE, *CONTORTYLENCHUS GENITALICOLA*, IN THE CERAMBYCID HOST, *MONOCHAMUS ALTERNATUS*, POPULATIONS

H. Kosaka and N. Ogura

Forest Biology Division, Forestry and Forest Products Research Institute, Tsukuba Ibaraki, Japan

Contortylenchus genitalicola Kosaka and Ogura is an entomophagous and mycetophagous nematode parasitizing the Japanese pine sawyer, *Monochamus alternatus* Hopc. *M. alternatus* is a serious forest pest because it transmits the pine wood nematode, *Bursaphelenchus xylophilus* (Steiner and Buhner), a causal agent of severe pine wilt disease in eastern Asia. *C. genitalicola* is considered a candidate biological control agent against *M. alternatus* since this nematode reduces reproductive potential of its host.

Geographical and spatial distribution of *C. genitalicola* in *M. alternatus* populations was investigated to know the nematode parasitism more clearly. *C. genitalicola* was found in adult *M. alternatus* populations from various parts of Japan. For instance, *C. genitalicola* was isolated from *M. alternatus* adults in Kumamoto pref., southern part of Japan, and in Akita pref., northern limit of the insect distribution. Prevalence of *C. genitalicola* in *M. alternatus* populations from Kamisu, Ibaraki pref., central part of Japan, during 5 years was about 5 % in each year. Spatial distribution of *C. genitalicola* in *M. alternatus* populations from Kamisu was aggregated or over-dispersed and the distribution fitted to the negative binomial.

21-034

STEINERNEMA KUSHIDAI, A NOVEL BIOLOGICAL CONTROL AGENT FOR THE SOIL LIVING COLEOPTERAN BEETLES

M. Tachibana, A. Fujiie¹, N. Suzuki, I. Asano, L. Indrasith

Kubota Corporation Advanced Technology Laboratory, Ibaraki, Japan – 1 Chiba Prefectural Agricultural Experiment Station, Chiba, Japan

S. kushidai, an entomopathogenic nematode, which was found in Japanese soil in 1984, showed the high activity against various Coleopteran beetles. In Japan the Coleopteran beetles are a major group of insects that feed on the roots of economically important crops, such as turfgrass, sweet potatoes and peanuts. We could maintain the nematodes in highly active form and make progress in research areas such as mass-fermentation and formulation.

S. kushidai has a wide insecticidal spectrum against beetles dwelling in Japanese soil. The nematodes showed high activity between 20-30°C, which is similar to larvae's general feeding behavior. This suggests that nematodes generally penetrate the larval body through the mouth.

We applied the formulated nematodes into turfgrass field of golf courses at the rate of 250,000-500,000 nematodes/m² and could observe high mortality of the beetles after 2-4 weeks post treatment. The nematodal density in the soil increased 6 times during this period, indicating the occurrence of secondary infection in the field.

21-033

POTENTIAL FOR USE OF ENTOMOPATHOGENIC NEMATODES AGAINST TEPHRITID FRUIT FLIES

M. Heath and R. R. Heath

2111 SW 91st St, Gainesville, FL USA

Insect Attractants, Behavior and Basic Biology Research Laboratory, USDA-ARS, Gainesville, FL USA

Caribbean fruit flies, *Anastrepha suspensa* (Loew), are susceptible to infection by heterorhabditid nematodes. Laboratory studies have yielded infected larvae, pupae, and adults. The larval stage, however, would be the most likely stage to target in a biological control program as it is most susceptible to infection and infective juveniles can easily exit the host for recycling in a soil environment. Adequate soil moisture is critical for optimal activity of soil dwelling entomopathogenic nematodes. The use of entomopathogenic nematodes as a component of a biorational IPM program (such as use with food based attractants) against these pest insects warrants further investigation.

21-035

EFFICIENCY OF *HETERORHABDITIS BACTERIOPHORA* POINAR (NEMATODA: HETERORHABDITIDAE) UNDER INSECTICIDE-STRESS IN PARASITIZING *SPODOPTERA LITURA* FABR. (LEPIDOPTERA: NOCTUIDAE).

S.S. Sehgal, Varsha Baweja

Department of Zoology, University of Delhi, Delhi-7, India

The present work is an attempt to assess the biocontrol potential of *Heterorhabditis bacteriophora* against *Spodoptera litura* larvae, which are often treated with malathion for their control in the fields. This insecticide mostly washed down in the soil. Motility of infective juveniles (IJs) of *H. bacteriophora* was recorded in terms of number of undulations per minute to ascertain their vitality after exposing to various sublethal concentrations of malathion. The IJs showed incomplete undulations as well as decreased motility with the increase in malathion concentration. Infectivity tests were conducted using filter paper bioassay. The reduced parasitization rate with respect to *S. litura* larvae with increasing concentrations of malathion manifested negative correlation between IJs of *H. bacteriophora* and various concentrations of malathion. Malathion treated larvae of *S. litura* were also found to be suitable hosts for *H. bacteriophora*. The potential of *H. bacteriophora* is discussed towards insect pest suppression in IPM.

21-036

AGGRESSIVENESS AND SPECIFICITY OF ARGENTINEAN *STEINERNEMA* AND *HETERORHABDITIS* SPECIES.

M. A. de Doucet¹, E. Trumper², A. Bertolotti¹, A. Giayetto¹, M. Miranda¹ and R. Siemer¹. ¹ Centro de Zoología Aplicada Universidad Nacional de Córdoba. CC 122. 5000 Córdoba, ² Estación Experimental Agropecuaria, Instituto Nacional de Tecnología Agropecuaria, Manfredi, 5988 Córdoba, Argentina.

Entomopathogenic nematodes that belong to *Steinernema* and *Heterorhabditis* species, are promising agents in the control of insect pests. Recently, several isolates characterized by a higher infectivity have been detected in Argentina: *S. rara*, *S. glaseri* (respectively from Noetinger and Los Chorrillos, Córdoba) and *H. bacteriophora* (from Rio Negro). In order to know the host range, experiences were carried out in laboratory conditions to evaluate the aggressiveness and specificity of these autocton isolates. Different species of insects (n = 33) (larvae, nymphs and/or adults) were put in contact with infectives larvae. The mortality caused by the nematode and its development were registered. According to the species of nematodes, the insect class, its stage, and its feeding habits, the infectivity and degree of development of nematode were different. All the lepidopterans considered (agricultural pests) were attacked and they appeared as excellent hosts. In contrast, the aquatic dipterous were resistant. All species of coleopterans and homopterous considered were attacked except *Astylus atromaculatus* and *Aphis gossypii*. The hematophagous insects were rarely infected, and the development of nematode were limited. Generally, the larvae appeared more susceptible than the adults. Considering the results obtained the isolates tested would be considered in the biological control of harmful insects.

21-038

INFLUENCE OF ENTOMOPATHOGENIC NEMATODES ON THE PREDATORS BEETLES (CARABIDAE)

M. Jaworska and D. Ropek

Department of Agricultural Environment Protection, Academy of Agricultural, Mickiewicz Ave., 21, 31-120 Cracow, Poland

The effect of *Steinernema carpocapsae* and *Heterorhabditis bacteriophora* on mortality of *Bembidion properans*, *B. lampros*, *Pseudophonus pubescens*, *Pterostichus vulgaris* and *P. cupreus* was studied in the laboratory conditions. Invasive larvae in dose 1000 nematodes per insect were applied into the soil in plastic cups, in which the imagines of Carabidae were separately kept. Also effect of the food previously contacted with nematodes on the mortality of predators beetles was simultaneously studied. Both nematodes introduced into the soil and food infected with nematodes and consumed by Carabidae increased the mortality of imagines after three weeks. Semi - field trials showed that *Bembidion lampros* and *B. properans* were little susceptible to these nematodes. In field trials with using *S. carpocapsae* against two species of carabids from annual legumes *B. properans* and *Pterostichus cupreus*, most often captured into pitfall traps, no effect was found in case of different doses of invasive larvae on the soil surface.

21-037

PREVALENCE OF HIERARCHICAL RESPONSES TO HOST CUES AMONG ENTOMOPATHOGENIC NEMATODE SPECIES

E.E. Lewis

Department of Entomology, University of Maryland, College Park, MD USA

The response of entomopathogenic nematodes to host cues is closely linked with their foraging strategy. Lewis et al. (1995; Parasitology 110: 207-213) found that *Steinernema carpocapsae*, an ambushing forager, responds to host chemicals only when they are encountered in a specific order: contact with host cuticle stimulates attraction to volatile cues emanating from the host. In the same study *S. glaseri*, a cruise forager, was found to respond to either contact or volatile cues with or without a primer stimulus. *Steinernema feltiae* responded in an intermediate manner to combinations of host cues. *S. feltiae*'s responses to host cues offered individually was stronger than that of *S. carpocapsae* but weaker than *S. glaseri*, and exposure to host cuticle increased attraction to volatile cues. In the present study, the response to hierarchical orders of hosts cues is examined for several species of entomopathogenic nematodes including *S. scapterisci*, *S. riobravensis* and *Heterorhabditis bacteriophora*. Infective stage juveniles were tested for their attraction to host volatile cues either immediately after exposure to contact with *Galleria mellonella* cuticle for 30 minutes or without this contact. This study had two objectives. The first was to test the hypothesis that all nematode species that nictate, an ambushing behavior where the nematode elevates 95% of the body from the substrate, should respond to host cue hierarchies similarly to *S. carpocapsae*. The second objective was to examine more nematode species with "intermediate" foraging strategies (*S. riobravensis*, for example) to determine the commonality of the hierarchical response.

21-039

EFFECT OF INSECT HOST ON SUBSEQUENT INVASION OF ENTOMOPATHOGENIC NEMATODES

I. Glazer

Department of Nematology, ARO, The Volcani Center, Israel.

The phenomenon that only part (10-40%) of the nematode population invade the target host has been recorded in many studies. It has been mainly ascribed to differences in the ability of individual nematodes to infect. In the present study the effect of an infected host, the wax moth *Galleria mellonella*, on subsequent infection of the entomopathogenic nematodes *Steinernema carpocapsae* Mexican, *S. riobravensis* and *S. feltiae* was evaluated.

The invasion rate of the three nematode species to a non-infected host was reduced by 40-60% after pre-exposure to infected hosts. These nematodes regained their full invasion potential after they were rinsed with water. Invasion into insects which were previously injected with nematodes was significantly reduced by 60-80% 6-9 h after injection. The reduction in subsequent invasion due to the initial infection was nematode species-specific. This phenomenon was also observed with other lepidopteran pests (*Helicoverpa armigera* and *Spodoptera littoralis*).

The data indicate that the initial infection by entomopathogenic nematodes induced the release of a substance which reduced the subsequent invasion. The chemical and biological characteristics of this substance are currently under investigation.

21-040

EFFECTS OF THE TSETSE DNA VIRUS ON THE ULTRASTRUCTURE AND FUNCTIONS OF THE ACCESSORY REPRODUCTIVE GLAND IN THE HOST FLY *GLOSSINA MORSITANS CENTRALIS* (DIPTERA: GLOSSINIDAE)

R. C. Sang, W. G. Z. O. Jura¹ L. H. Otieno¹

Kenya Medical Research Institute Virus Research Centre, Nairobi, Kenya - 1 International Centre for Insect Physiology and Ecology, Nairobi Kenya.

Third instar *Glossina morsitans centralis* larvae were infected with the tsetse DNA virus by microinjection and at emergence adult males were fed every other day for 8 days and comparative observations made on some physical parameters, functions and the ultrastructure of the accessory reproductive glands (ARG) in infected and control flies. The ARG from control flies were found to be milky in appearance while those from virus infected flies were mostly transparent. The ARG from virus infected males had significantly smaller diameters ($F=200.4$, $P<0.0001$) than those of controls.

The uteri of females mated to virus infected males were either empty or contained partially formed spermatophore while uteri of females mated to control males contained fully formed spermatophore.

Histological studies of ARG tissues from virus infected males revealed some lesions in the epithelial cell layer characterised by degeneration of cytoplasmic organelles, vacuolation in the cytoplasm and detachment of the muscle layer from the basal plasma membrane.

21-042

ELECTRON MICROSCOPY OF A MALAYSIAN ISOLATE OF BACULOVIRUS FROM *SPODOPTERA LITURA* FAB.

¹Norani Abdul Samad, ¹Nafizah M. Noor and ²A. Said Sajap

¹Dept. of Biochemistry and Microbiology, ²Dept. of Forest Management Universiti Pertanian Malaysia, 43400 Serdang, Selangor, Malaysia.

The morphology and histopathology of a nuclear polyhedrosis virus (NPV) isolated from *Spodoptera litura*, the polyphagous leaf-eating caterpillar, were studied by transmission electron microscopy. The purified polyhedra had a spherical to oval outline measuring about 1.9-2.8 μm in diameter. Within the proteinaceous capsule or polyhedra many virions were observed and within each virion more than one nucleocapsid per envelop that appeared to be the MNPV type of the genus *Nucleopolyhedrosis*. Treatment with chemical detergent resulted in the release of the rod-shaped nucleocapsid measuring about 500 nm in length and 110 nm in diameter. Development of the NPV after 3 days post feeding of the polyhedra inclusion bodies (PIBs) was shown in thin sections of the infected larva fat body tissues. A number of PIBs were found in the nucleus with various size and shape. These were the occluded phenotypes which matured in the nuclei and contained many enveloped virions. Each of the virion supported several nucleocapsids, some as many as six. At later stages between four to six days post feeding of the PIBs the virogenic stroma gave rise to virus nucleocapsids which were single nucleocapsids. These were the second phenotype of virions that budded from the plasma membrane into the cytoplasm of infected cells.

21-041

TRANSMISSION DYNAMICS OF AN INSECT-VIRUS INTERACTION

Simão D. Vasconcelos^{1,2}, Jennifer S. Cory¹; Trevor Williams¹ & Rosemary S. Hails¹

1 - Ecology and Biocontrol Group, NERC Institute of Virology and Environmental Microbiology, Mansfield Road, Oxford, UK.

2 - University of Oxford, Department of Zoology, South Parks Road, Oxford, UK.

Information on the factors which influence virus transmission in insect populations can contribute to the optimal use of these agents as biopesticides as well as to the understanding and prediction of virus epizootics. However, quantitative studies on virus transmission are rare, and tend to be concentrated on forest pests.

In a series of field trials, the transmission dynamics of an agricultural pest (*Mamestra brassicae* L., Lep: Noctuidae) and its nucleopolyhedrovirus (Family *Baculoviridae*) was investigated. Densities of host and pathogen were manipulated in cabbage plots. Virus acquisition was estimated by destructive sampling at periodic intervals. Mortality increased with time of exposure to inoculum and with densities of host and virus. Times to death for each treatment and the transmission rates were estimated using mathematical models.

21-043

PATHOGENICITY AND CHARACTERISTICS OF *SPODOPTERA LITURA* NUCLEAR POLYHEDROSIS VIRUS FROM PENINSULAR MALAYSIA

Ahmad S. Sajap¹, James R. Kotulaj¹, Norani A. Samad²

M. Y. Hussein³, Hussan A. Kadir⁴

¹Department of Forest Management, ²Department of Biochemistry,

³Department of Plant Protection, Universiti Pertanian Malaysia, Malaysia

⁴Malaysian Agriculture Research and Development Institute, Malaysia

Spodoptera litura (Fabricius) is a cosmopolitan polyphagous insect pest of many food crops and tobacco. As in most other parts of the tropic, these armyworms are subject to a disease caused by a nuclear polyhedrosis virus (NPV) infection in the field. In Malaysia, no record of such an infection has been reported. Only recently, however, an epizootic of NPV disease occurred in *S. litura* population attacking tobacco crop in Kelantan, Malaysia. The incidence indicated that natural control of *S. litura* by NPV was operating in the tobacco ecosystem in the absence of a prophylactic insecticidal treatment. Though the impact of the disease on the *S. litura* population has yet to be known, NPV has the potential to be used as a control agent to be incorporated in management of *S. litura* in Malaysia. A study on the characteristics of the NPV was carried out. The result shows that the virus was pathogenic and specific to its host. It caused 96% larval mortality within a period of 10 days at a dosage of 6×10^8 PIBs/larva and had no adverse effect on Lepidoptera, *Spirama retorta* Clerck (Noctuidae) and bagworm *Pteroma pendula* Joannis (Psychidae). The length of the virus DNA was in the range of 109 to 151 kilobase pairs. This was identical to those of DNAs in other *Spodoptera* viruses; *S. exigua* NPV and *S. frugiperda* NPV.

21-044

VIRAL EPIZOOTICS INDUCED BY THE GRANULAR VIRUS IN *PLODIA INTERPUNCTELLA* HB.

M.Chukhrii, C.Beratlieff, F.Jianu, M.Bigiu
Research Institute for Plant Protection
71592-Bucharest, Romania

Plodia interpunctella Hb. is a major polyphagous storage pest attacking grain, dried fruits and especially those included in chocolate, causing severe damages.

Controlling this pest with chemicals is inadequate, therefore alternative non-toxic means to regulate population densities, safe to man and environment unpolluting seem to be useful.

One of the most efficient option could be the use of baculoviruses, having no negative influences on other components of storage biocenoses and to human safeguard.

Till now, two groups of viruses have been detected in *P.interpunctella*:

- the nuclear polyhedrosis virus (NPV);
- the granulosis virus (GV).

In *P.interpunctella* populations occurring in Romania, laboratory-reared for several years on suitable diets, only the granular virus (GV) has been detected. Trials have demonstrated that the larval mortality in L-3 and L-4 instars caused by this virus at 26-27°C reached 90-95%. Peak of mortality caused by viral infections nearly in all larval instars has been noted 8-9 days after the infection start.

These data suggest a prospective to elaborate a new viral product destined to regulate population densities in *P.interpunctella*.

21-046

FIELD-BASED RISK ASSESSMENT OF GENETICALLY MODIFIED BACULOVIRUSES IN TARGET AND NON-TARGET HOSTS

J. S. Cory, R. S. Hails, P. Hernández-Crespo, S. M. Sait & B. M. Green

Ecology and Biocontrol Group, NERC Institute of Virology and Environmental Microbiology, Mansfield Road, Oxford, OX1 3SR, UK

Insect pathogens show great potential as pest control agents, however, their use has been limited because of their relatively slow speed of action. Genetic engineering is perceived as a means whereby their insecticidal potential can be enhanced. Field trials have shown that the application of a baculovirus which expresses an insect-selective toxin results in a more rapid kill and in reduced crop damage as compared to the unmodified wild type. Before these organisms are released into the environment on a wide scale any risks attached to their release must be assessed. Using a virus expressing an insect-selective toxin derived from a scorpion as a model system, contained field trials were run to compare the effect of the recombinant virus and its parent wild-type on lepidopteran hosts which varied in susceptibility. Virus was introduced in two ways; as a spray (like an insecticide application) and as infected cadavers (the major route for transmission in insect larvae). As expected, virus-induced mortality was much lower in the less susceptible host species in both treatments. However, in the spray trial the mortality induced by both viruses was equal whereas in the cadaver trial the scorpion toxin virus produced significantly less mortality than the wild-type. This is because the larvae infected with the recombinant virus become paralysed and tend to fall off the crop plant, thereby removing the inoculum from other healthy larvae. These results indicate that transmission of these toxin-expressing baculoviruses will be considerably reduced in the field.

21-045

FORMATION OF OCCLUSION BODIES OF NUCLEAR POLYHEDROSIS VIRUSES IN THE INFECTED CELLS OF *MALACOSOMA NEUSTRIA* L. (LEPIDOPTERA: LASIOCAMPIDAE).

L. Jankevica, Z. Cudare

Department of Experimental Entomology, Institute of Biology, Latvian Academy of Sciences, Salaspils, Latvia

Baculoviruses rather rarely cause epizootics in pest populations under Latvian climatical conditions. Nuclear polyhedrosis viruses have been isolated from 7 insect species. *Malacosoma neustria* L. has been used as a model insect in the cytological researches.

Infectious process of *M. neustria* caused by the Latvian isolate of *Malacosoma neustria* nuclear polyhedrosis viruses (Mn NPV) was investigated. The LD50 values were 75 and 985 polyhedral occlusion bodies (polyhedrae) per larvae of the second and third instars, respectively. Tissue and cells in the latest stage of the disease after per os infection content a large amount of viral polyhedrae. Electron microscopy shows that at the 6th day after infection polyhedrae, multiple virions and nucleocapsids are visible in the nucleus of gut epithelial and fat cells. The dimension of polyhedra is 900-5000 nm. Rod-shaped nucleocapsids are 220 - 360 nm in length and 30 - 60 nm in width. Polyhedrae of the MnNPV Latvian isolate content multiple virions, which content 2-6 nucleocapsids each. The development process of the membrane of virions and polyhedrae has been investigated. In particular cases polyhedrae have been observed with necrotical changes.

Obtained results of the natural way of polyhedrae formation will give the possibilities to estimate the influence of substances used in virus preparation, on this process. The influence of inhibitors and stimulators will also be determined.

21-047

COMPARISON OF INFECTIVITY, TIME-TO-DEATH AND PRODUCTIVITY BETWEEN THE WILD TYPE AND RECOMBINANT BACULOVIRUSES IN HOSTS DIFFERING IN SUSCEPTIBILITY

P. Hernández-Crespo, S.M. Sait, R.S. Hails, J.S. Cory

Ecology and Biocontrol Group, NERC Institute of Virology and Environmental Microbiology, Oxford, UK.

A genetically modified baculovirus encoding a scorpion toxin gene, which reduces the survival time of its host, was compared with its parental wild type clone in laboratory assays. Early second instar larvae of *Trichoplusia ni* (a permissive species) and *Mamestra brassicae* (a semi-permissive species) were infected at different concentrations with both viruses. LC50 values did not differ significantly between viruses, but were lower for *T. ni* than for *M. brassicae*. Survival time and virus yield were lowest when *T. ni* was infected with the recombinant virus. In all treatments, the yield:weight relationship was shown to be a complex interaction between dose, virus type and host species, suggesting that virus yield cannot be estimated from weight alone. Although the recombinant virus reduced the mean time to death, yield of virus was reduced as a consequence. This has implications for the fitness of the virus in the field.

21-048

BEHAVIOURAL CHANGES IN BACULOVIRUS-INFECTED *MAMESTRA BRASSICAE* L. (LEP: NOCTUIDAE) LARVAE AND THEIR RELEVANCE TO THE SPATIAL SPREAD OF INOCULUM

Simão D. Vasconcelos^{1,2}, Rosemary S. Hails¹ & Jennifer S. Cory¹

1 - Ecology and Biocontrol Group, NERC Institute of Virology and Environmental Microbiology, Mansfield Road, Oxford, UK.

2 - University of Oxford, Department of Zoology, South Parks Road, Oxford, UK.

The effect of baculovirus infection on the mobility of 2nd and 4th instar *M. brassicae* larvae was investigated in the laboratory and field. BV infection clearly altered larval mobility, with the changes in behaviour varying with the timecourse of infection. Diseased larvae moved 3 to 5 times further than healthy ones during the middle stages (4 days) of infection. By the 7th day post-infection diseased larvae were less mobile than healthy counterparts. The same pattern of modified behaviour was observed in both instars.

In the field, infected larvae tended to die on the apex of the cabbage leaves. Bioassay of the leaves showed that there was a linear decrease of inoculum from central to peripheral plants within the plots, which occurred to the same extent for 2nd and 4th instars. Leaves from plots where infected 4th instar larvae had been introduced had higher inoculum density than plots with 2nd instars.

21-050

INTERACTION BETWEEN *APANTELES KARIYAI* WATANABE (HYMENOPTERA: BRACONIDAE) AND AN ENTOMOPOXVIRUS IN THEIR HOST *PSEUDALETIA SEPARATA* (WALKER) (LEPIDOPTERA: NOCTUIDAE)

Y. Kunimi, G. K. Kyei-Poku, H. Tanaka

Department of Applied Biological Science, Faculty of Agriculture, Tokyo University of Agriculture and Technology, Fuchu, Tokyo, Japan

The common armyworm *Pseudaletia separata* is subjected to control by its sympatric natural enemies *Apanteles kariyai* and an entomopoxvirus (PsEPV) in its natural habitat. The possible interactions between these control agents were studied in the laboratory to examine the effect of PsEPV infection of the host on parasitoid survival.

The fate or survival to maturity of *A. kariyai* in entomopoxvirus infected *P. separata* larvae was affected by the time of parasitization prior to the inoculation of the host with PsEPV.

The number or proportion of parasitoids that survived and emerged to form cocoon increased as the period between oviposition and virus infection increased. Parasitoids could not kill host larvae and emerge as adult wasps if they develop in host that were exposed to PsEPV in less than 5 days after parasitization.

The development of the parasitoid *A. kariyai* within PsEPV-infected *P. separata* was adversely affected and this effect occurs prior to host death.

21-049

NUCLEOTIDE SEQUENCE OF FUSOLIN GENE OF *ANOMALA CUPREA* ENTOMOPOXVIRUS (AcEPV)

W. Mitsuhashi and M. Sato

National Institute of Sericultural and Entomological Science, Tsukuba, Japan

A larva of the cupreous chafer, *Anomala cuprea* is a major pest in many crops and forest trees in Japan. A pathogenic entomopoxvirus of this insect, AcEPV, may be considered as a potential biocontrol agent. In this study, the nucleotide sequence of major protein of spindle, fusolin, was investigated. The molecular size of fusolin was estimated as 46 kDa from the analysis of SDS-PAGE. When PCRs (polymerase chain reactions) were tried using the many primer sets constructed from the sequence data of the fusolin gene of *Melolontha melolontha* entomopoxvirus (MmEPV) (Gauthier *et al.*, 1995), only one primer set was available to amplify a part of AcEPV fusolin gene. This 0.3 kb PCR product was sequenced and a new primer set was constructed from the resultant data for inverse PCR elongating towards both upstream and downstream of the PCR product. The inverse PCR product was cloned into pBluescript II and its deletion series were sequenced. The homology (matching percentage) between AcEPV and MmEPV fusolin gene was about 75%, which was lower than that (ca. 90%) of spheroidin homology. From the result, the biological importance of spindle was thought to be smaller than the spheroid, though the biological significance of the former was remained unknown.

21-051

AN INVESTIGATION INTO THE PERSISTENCE AND INTERACTION OF TWO VIRUSES OF *AGROTIS SEGETUM* (D.&S.) (LEPIDOPTERA: NOCTUIDAE) IN THE DEVELOPMENT OF LONG TERM CONTROL STRATEGIES.

K. Wilson^{1,2}, M. R. Speight², J. S. Cory¹.

1 NERC Institute of Virology and Environmental Microbiology, Mansfield Road, Oxford, UK, OX1 3SR - 2 Department of Zoology, University of Oxford, South Parks Road, Oxford, UK, OX1 3PS.

The common cutworm, *Agrotis segetum* (Denis & Schifferrmüller), is a highly polyphagous and widespread pest. It is one of a number of noctuid moths whose larvae live mainly in the soil during later instars, feeding by severing stems and boring into roots and tubers. Its soil-dwelling behaviour makes it a difficult target for chemical sprays and larvae may remain undetected until severe damage has occurred.

Baculoviruses represent an important and effective alternative for cutworm control. The soil acts as a reservoir for virus between larval outbreaks and protects inclusion bodies against environmental degradation. Larvae may ingest inclusion bodies from this site, and so by maximising soil persistence, immediate effective control may be achieved in subsequent generations. In a two-year field trial, it was shown that a granulovirus of *A. segetum* showed greater persistence than a nucleopolyhedrovirus or a combination of the two and that no interaction occurred in mixed infections.

21-052

INSECT SMALL RNA VIRUSES OFFER NEW STRATEGIES IN PEST CONTROL.

K.H.J. Gordon, A.L. Bawden, S.J. Dorrian, M.R. Lincoln, P. Larkin* and T.N. Hanzlik

CSIRO Divisions of Entomology and *Plant Industry, Canberra, ACT, Australia.

Insects are host to a number of small non-enveloped RNA viruses which offer new approaches to pest control. Modern techniques of genetic engineering allow the specificity, simplicity and unique properties of these viruses to be exploited by producing them in non-host systems such as in transgenic plants. We are exploring the potential of a recently characterised tetravirus, *Helicoverpa armigera* stunt virus (HaSV), for the control of heliothine pests including the cotton bollworm. Upon ingestion by neonate larvae, this virus is specific for cells of the midgut and rapidly causes the larvae to cease feeding, so that they become stunted and die. Its genome consists of only 3 genes on 2 strands of RNA. We have constructed synthetic virus genes designed to produce infectious virus particles in non-hosts such as plants or insect cells infected using a baculovirus vector. Initial data from transgenic plants indicate the efficacy of this approach: assembly of infectious, pest specific virions in the plants is able to protect them against feeding damage.

21-054

DISTRIBUTION AND ABUNDANCE OF SOIL-BORNE NUCLEAR POLYHEDROSIS VIRUSES (NPV: BACULOVIRIDAE) INFECTING THE COTTON BOLLWORM, *HELICOVERPA ARMIGERA* (HÜBNER) (LEPIDOPTERA NOCTUIDAE) IN EASTERN AUSTRALIA

A.R. Richards, P.D. Christian

Commonwealth Scientific and Industrial Research Organisation, Division of Entomology, Black Mountain, GPO Box 1700, Canberra ACT 2601, Australia

Data on the natural abundance of insect pathogens in the soil environment is scarce even though the soil is thought to play an important role in the long-term persistence and transmission of such pathogens in host populations. A bioassay method employing the direct incorporation of soil samples into an insect diet has provided a rapid and convenient method for estimating the loading of soil-borne *Helicoverpa* NPVs in the Australian agro-ecosystem.

Lethal concentration curves for HaSNPV against 24 hour old *H. armigera* larvae have been constructed for different rates of soil incorporation (0.005g soil/ml diet at the lowest rate up to 0.25g soil/ml diet) This method provides consistent detection of virus down to a level of <50 PIBs/g soil. In addition, amplification of NPV DNAs from infected cadavers using the polymerase chain reaction (PCR) technique, followed by restriction endonuclease analysis of the PCR product, allows rapid genotyping of the naturally occurring isolates. Using selected oligonucleotide primers, separation of very closely related NPVs (<2% nucleotide divergence) has been possible. Data obtained from soil-NPV surveys conducted in eastern Australia, with samples from a diversity of cultivated and non-cultivated sites, will be presented.

21-053

PERSISTENCE, DISPERSAL AND TRANSMISSION OF A NUCLEAR POLYHEDROSIS VIRUS (NPV: BACULOVIRIDAE) INFECTING THE COTTON BOLLWORM, *HELICOVERPA ARMIGERA* (HÜBNER) (LEPIDOPTERA: NOCTUIDAE) IN AUSTRALIAN COTTON

A.R. Richards, P.D. Christian

Commonwealth Scientific and Industrial Research Organisation, Division of Entomology, Black Mountain, GPO Box 1700, Canberra ACT 2601, Australia

Field and laboratory studies employing wild-type *Helicoverpa* NPVs are providing the basis for the design of environmental monitoring protocols for the release of genetically modified viruses. Using simple bioassay approaches for virus detection combined with a PCR-REN technique for virus identification, experiments to date have focused on three major aspects of insect-pathogen ecology: persistence, dispersal and transmission.

In the first case, data on the rate of virus decay in the cotton leaf canopy and in the soil beneath the canopy have shown that NPV half-life values are strongly dependent on the position of virus in the canopy as well as crop growth stage. The pattern of virus dispersal across the field surface following irrigation was shown to follow a logarithmic fall off in NPV activity with distance from virus source. Soil cores from field plots and laboratory experiments using soil columns indicated little propensity for NPV to disperse vertically through the soil profile. In the virus transmission study, the importance of the soil as a virus reservoir for the translocation of NPV to host feeding sites and subsequent transmission in the host population was addressed. The significance of these data and of the approaches adopted will be discussed with respect to the environmental impact assessment of genetically modified insect viruses.

21-055

MORPHOLOGICAL AND MOLECULAR CHARACTERIZATION OF MICROSPORIDIA FROM FIRE ANTS

B. A. Moser, J. J. Becnel¹, J. Maruniak, R. S. Patterson

Dept. of Entomology and Nematology, University of Florida, Gainesville, FL, USA - ¹ USDA-ARS, Gainesville, FL, USA

Two species of imported fire ants, the black imported fire ant *Solenopsis richteri* and the red imported fire ant *S. invicta*, were introduced into the United States from South America in the early part of this century. *Solenopsis richteri* has a limited distribution but *S. invicta* has spread throughout the Southern United States. It is considered a major agricultural and urban pest in the US but not in its home lands of South America. This may be due, in part, to the lack of natural enemies and competitors in the US. Expeditions to South America seeking natural enemies have yielded two microsporidia, *Thelohania solenopsae* and *Vairimorpha invicta*, both described from *S. invicta* in Brazil. Morphologically similar microsporidia (*Thelohania* sp. and *Vairimorpha* sp.) have been reported from a high proportion of *S. richteri* collected in Argentina. Their role as biological control agents for *S. invicta* in the US is being investigated but transmission trials with these microsporidia have been unsuccessful. A fundamental question, therefore, is to determine if *T. solenopsae* and *V. invicta* are conspecific with *Thelohania* sp. and *Vairimorpha* sp. Furthermore, since microsporidia with several spore types are known, we investigated the possibility that *Vairimorpha* sp. and *Thelohania* sp. could be different phenotypes of the same species. Morphological characterization using light and electron microscopy together with molecular analysis of the 16S rRNA gene sequences were employed to compare the species.

Gross morphology and ultrastructural comparisons could not distinguish *T. solenopsae* from *Thelohania* sp. or *V. invicta* from *Vairimorpha* sp. Comparison of the 16S rRNA gene sequences between *T. solenopsae* and *Thelohania* sp. demonstrated a sequence similarity of more than 99%. Based on this data, *T. solenopsae* and *Thelohania* sp. are conspecific or represent two subspecies. Molecular data are not available but required for *V. invicta* in order to determine whether *V. invicta* and *Vairimorpha* sp. are conspecific or represent two subspecies.

The two *Thelohania* spp. and two *Vairimorpha* spp. are distinct from each other morphologically. *Thelohania* sp. and *Vairimorpha* sp. from *S. richteri* share a sequence similarity of only 63%. These data show that *Thelohania* sp. and *Vairimorpha* sp. are distinct species in separate genera.

21-056

THE CHARACTERIZATION OF *NOSEMA LITURAE* ISOLATED FROM TAIWAN

S. J. Tsai and C. H. Wang

Department of Plant Pathology and Entomology, National Taiwan University, Taipei, Taiwan, R.O.C.

The epizootic disease causing death in *Spodoptera litura* (Lepidoptera: Noctuidae) occurring in Taiwan at fall season in every year was shown to be caused by *Nosema liturae*. Structural properties of this microsporidia were examined by electron microscopy, polyacrylamide gel electrophoresis, immunoblot assay and restriction endonuclease analysis and compared with other *Nosema* isolates from other pests, *S. exigua*, *Helicoverpa armigera*, *Plutella xylostella*, and *Pieris* spp., and with *Pleistophora anguillarum* from eel. The results had shown that no significant difference between *N. liturae* and other *Nosema* isolates, but no any relation with *P. anguillarum*, was found. Bioassays of *N. liturae* gave LD₅₀ values 1.1×10^4 for third-instar larvae of *S. litura* and was not found to differ significantly from other *Nosema* isolates. We suggest that five isolates of *Nosema* spp. are closely related genetically.

21-058

INFECTION AND DEVELOPMENT OF *NOSEMA LITURAE* (MICROSPORA) IN IPLB SF-21AE CELL LINEC. H. Wang¹, S. J. Tsai¹, C. F. Lo²

¹ Department of Plant Pathology and Entomology, National Taiwan University, Taipei, Taiwan, R.O.C.- ² Department of Zoology, National Taiwan University, Taipei, Taiwan, R.O.C.

Tissues collected from tobacco cutworm (*Spodoptera litura* Frabricius) experimentally infected with *Nosema liturae* were cocultivated with IPLB SF-21AE cells in TNM-FH medium. The in vitro cultivation system of this microsporidian was successfully established. The SF-21AE cells were found to be persistently infected with this entomopathogen and the healthy cells were supplemented at a period of about one month according to the infection rate. With this cultivation system, the life cycle of this entomopathogen achieved within 2 weeks and the infective merozoites which were capable of proceeding to further infection were released persistently from infected cells. Using histochemical, technique, indirect immunofluorescent assay and electron microscopy, several developing stages could be distinguished. The results of the present in vitro cultivation system could provide an available tool for studding microsporidian and spores free from other entomopathogen contamination.

21-057

INFECTION OF *HELICOVERPA ZEA* (LEPIDOPTERA : NOCTUIDAE) LARVAE AND CULTURED CELLS WITH "FEW-COILED SPORES" OF *NOSEMA FURNACALIS* (MICROSPORA : NOSEMATIDAE)H. Iwano, T. J. Kurti¹ and U. G. Munderloh¹

Department of Plant Resource Science, Nihon university, kameino, Fujisawa, Japan - ¹ Department of Entomology, University of Minnesota, MN, USA

Our previous studies showed the population of *Nosema furnacalis* spores was consisted of "few-coiled spores" only, when harvested from cultured cells of *Helicoverpa zea* subcultured eighty times after inoculation of "many-coiled spores" of *N. furnacalis*. We report here those "few-coiled spores" can infect *H. zea* larvae, when injected subcutaneously without priming. Haemocytes were found to harbor developing stages of *N. furnacalis* one day after injection and many spores in various tissues 14 days after injection. Also, "few-coiled spores" could infect *H. zea* cultured cells without priming after the storage for one to three months at 5 °C.

21-059

PCR DETECTION OF MULBERRY DWARF DISEASE-PHYTOPLASMAS IN AN INSECT VECTOR, *HISHIMONAS SELLATUS* AND PHLOEM SAP COLLECTED BY LASER STYLECTOMY

M. Sato, W. Mitsuhashi, K. Watanabe and H. Kawakita

National Institute of Sericultural and Entomological Science, Tsukuba, Japan

PCR (polymerase chain reaction) detection of mulberry dwarf disease-phytoplasmas (former mycoplasma-like organisms) in a rhombic-marked leafhopper, *Hishimonus sellatus* and phloem sap was investigated. Two sets of primer pair were used to amplify the target DNA fragment of 16S rRNA genes of phytoplasmas. The preparation of template DNA samples from insects was performed by CTAB method. PCR detection of phytoplasmas was possible in DNA samples prepared from a whole body of infected leafhopper but not in any samples from non-infected insects. The predicted band was also observed in samples prepared from a head, an abdomen and a pair of salivary gland of infected insects, respectively. Pure phloem sap was collected from diseased mulberry by laser stylectomy using *Ricania japonioca* and it was used directly as the DNA template. The predicted band was observed for phloem sap samples collected from diseased plants, but not for any samples collected from healthy plants. PCR products were shown to be the targeted DNA originated from phytoplasmas by analysis of their restriction enzyme digestion or nested PCR. Thus, PCR was very specific and sensitive to detect mulberry dwarf disease-phytoplasmas in the insect vector and phloem sap.

21-060

EFFECT OF COCCIDIA *Adelina* SP. (PROTOZOA: EUCCIDIA) ON TWO LARVAE CETONIINAE: *Cetonia aurata* (LINNE) AND *Oxythyrea funesta* (PODA)

By

A. KHARAZI-PAKDEL & P. ROBERT

An adelina (Protozoa:Eucocciida) strain isolated from *Cetonia aurata* Provoked a lowered fecundity and fertility in infected *C. aurata* and *Oxythyrea funesta* (Col:Scarabaeidae, Cetoniinae) females as compared to untreated females.

Transmission from host to host apparently occurs only Per os.

21-062

MICROBIOLOGICAL CONTROL OF *LYMANTRIA DISPAR* L. WITH *BACILLUS THURINGIENSIS KURSTAKI* IN SARDINIA SUPPORTED BY ECOLOGICAL STUDY

A. Lentini¹, P. Luciano¹, R. Prota²¹ Istituto di Entomologia agraria, Università di Sassari, Italy² Istituto di Ricerca sul Controllo Biologico dell'Ambiente, CNR, Sassari, Italy

Observations on the gypsy moth population dynamics have been carried out for over 30 years in Sardinian cork-oak forests. The defoliator fluctuation amplitudes varies from 11 to 5-6 years in different parts of the Island, probably influenced by the climatic conditions and by the composition of the plant communities in the environments studied. Several parameters characterizing each gradation phase of gypsy moth (egg population density, eggs/egg-cluster, fertile egg percentage and parasitism rates) have been obtained; they enable its population trends to be predicted and prove useful in programming pest control operations. In response to the ever-increasing awareness of the need to control the gypsy moth infestations, large cork-oak forest areas have been subjected to microbiological control tests, avoiding any upset to the delicate ecosystemic equilibrium. In particular, various preparations based on *Bacillus thuringiensis kurstaki* (Btk) were distributed aerially, to test their efficacy and the most suitable application modality to a Mediterranean environment. Accurate timing is essential: in the case of low infestations (2 larvae/branch tip), when at least 90% of the larval population consists of I and II instars, 32 BIU/ha determined more than 80% mortality. Application at 60 BIU/ha guaranteed effective control against the highest infestations (5 larvae/branch tip) causing more than 80% mortality. An important advantage is obtained from the application of the undiluted product at ULV, thereby providing aircraft productivity and reducing ground support requirements. In these experiments, *B. thuringiensis* did not prove to have any direct effect on the gypsy moth parasite and predator activity, whose incidence seemed to be dependent on host densities in treated and untreated areas.

21-061

LARGE SCALE USE OF NUCLEAR POLYHEDROSIS VIRUS IN BRAZIL TO CONTROL THE SOYBEAN CATERPILLAR, *ANTICARSIA GEMMATALIS* (LEP.:NOCTUIDAE).

F. Moscardi and D.R. Sosa-Gomez

EMBRAPA - National Soybean Research Center, Londrina, PR, Brazil.

A nuclear polyhedrosis virus (NPV) of *Anticarsia gemmatalis*, a key soybean defoliator in Brazil, has been used as a microbial insecticide since 1982. Initial use by farmers were based on crude preparations of the NPV, but a wettable powder formulation was developed and made available to the farmers since 1986. Presently, five private companies produce and commercialize the microbial insecticide, and its annual use is estimated at approximately one million hectares of soybean in the country. Analysis of temporal NPV isolates, collected each season after large-scale field applications, indicates that virulence was not significantly affected after more than ten years of virus use as a microbial insecticide. Also, resistance to the NPV could not be detected between *A. gemmatalis* populations collected from different regions in Brazil, even when comparing populations from sites where the NPV had been applied yearly with populations from sites with no history of virus applications. On the other hand, *A. gemmatalis* rapidly developed resistance to the NPV under selection pressure experiments in the laboratory, with resistance ratios reaching over 2,000. The implementation of the programme, the factors related to the success of the NPV as a microbial insecticide, and recent research developments will be discussed.

21-063

DIVERSITY OF NUCLEAR POLYHEDRAL VIRUSES ISOLATED FROM VARIOUS *LYMANTRIA DISPAR* L. POPULATIONS

M. Chukhrii¹, Gh. Mihalache², C. Cornei², H. Iliescu¹

1) Research Institute for Plant Protection, Bucharest, Romania;

2) Research Institute for Sylviculture, Bucharest, Romania

Nuclear Polyhedral Viruses isolated from *Lymantria dispar* L. as 3rd-4th instar larvae from Romania, West and East Ukraine, Yugoslavia, Kirgizia, USA and Canada have been examined.

To study diversity of baculoviruses the morphological data obtained by electron microscopy have been analysed. The main criteria were: average number of nucleocapsids included in one superpolyvirion (SPVC) and envelope features of SPVC (polyhedrons).

It was shown that NPV isolated from European and Asiatic populations included virions and polyvirions containing one nucleocapsid, three nucleocapsids (q1, q3 and q4). The NPV isolated from America presented only virions (q1), while q3 and q4 were not significant.

The total number of nucleocapsids in SPVC of NPV isolated from *L. dispar* populations in Europe and Asia was roughly 1,215 nucleocapsids, while only 723 in the American populations. These data are also correlated to biological activity, which was about twice higher in Euro-Asiatic populations.

21-064

ENTOMOGENOUS FUNGI IN RESOURCE MANAGEMENT IN SUSTAINABLE AGRICULTURE AND FORESTRY

B. Papierok
Institut Pasteur, Paris, France

Terrestrial entomogenous fungi are acting like efficient natural enemies of various pest insects. Several fungal species were, and still are given high interest because of their potential as "true" biological agents (which implies that inoculum could be artificially produced). Most of fungal entomopathogens, however, are unlikely to be used in this way in the near future. Given this, a strategy in the view of sustainable agriculture and forestry would be concomitantly, to act on any factor likely to favour the establishment and spread of beneficial fungi in insects populations, and to make sure that no cultural practice disadvantage these microorganisms.

Such objectives require intensive studies, which allow to specify, among others: the identity of naturally occurring entomogenous fungi in agroecosystems, forest areas and natural ecosystems, the importance of connections between these ecosystems, the host spectrum of these pathogens, their ecological requirements, their interactions with other microorganisms (especially in the soil), their susceptibility to cultural practices, first of all the use of pesticides.

These various aspects would be discussed on the basis of data originating from temperate and tropical areas as well, and involving various groups of fungi (Zygomycetes: order Entomophthorales; Ascomycetes: genus *Cordyceps*, and Hyphomycetes) and insects (mostly Hemiptera, Lepidoptera, Coleoptera, and Diptera) in.

21-066

BEAUVERICIN PRODUCTION BY ENTOMOPATHOGENIC FUNGI

A. Moretti, A. Logrieco, G. Zimmermann¹, A. Bottalico²
Istituto Tossine e Micotossine da Parassiti vegetali, C.N.R., Viale Einaudi 51, 70125, Bari – ¹ Institute for Biological Control, Federal Biological Research Centre for Agriculture and Forestry, Heinrichstrasse 243, D-64287 Darmstadt, Germany – ² Istituto di Patologia vegetale dell'Università, 07100, Sassari, Italy.

The capability to synthesize beauvericin, a well known bioactive cyclohexadepsipeptide with insecticidal properties, was investigated for various isolates of entomopathogenic fungal species, i.e. *Fusarium subglutinans* from *Ostrinia nubilalis* and *Scirpophaga excerptalis*; *Paecilomyces fumosoroseus* from *Eupithecia innotata*, *Carpocapsa pomonella* and *Melolontha melolontha*; *Beauveria bassiana* from *Pyrrhalta luteola*, *Hylotrupes bajulus*, *Costelytra zealandica*, *Ips typographus*, *Laodelphax striatellus*, *Thaumtopoea wilkinsonii*; *B. brongniartii* from *Holotrichia morosa*, *C. zealandica*, *M. melolontha* and *Balaninus nucum*; *B. felina* from *Anaitis efformata*; *B. vermiconia* from volcanic ash soil.

Fungi were cultured for 4 weeks at 25 °C on autoclaved husked rice kernels, a good substrate for beauvericin synthesis, and the chemical analysis was carried out on fungal cultural extracts by high performance thin layer chromatography (HPTLC) and confirmed by high performance liquid chromatography (HPLC). Beauvericin production among isolates of *Beauveria* species was variable, whereas *P. fumosoroseus* and *Fusarium* isolates produced beauvericin at high levels (up to 300 mg/kg dried culture).

The toxicity of the culture extracts toward brine shrimps (*Artemia salina*) was in general related to the occurrence of the beauvericin (LD₅₀ 3.6 µM), except for some *Beauveria* isolates. This finding led us to suspect that other metabolites are involved in *Beauveria* species toxicity.

21-065

CONTROL OF TERMITES USING ENTOMOPATHOGENIC FUNGI, *Beauveria bassiana* and *Metarhizium anisopliae*.

S.B. Alves¹, J.E.M. de Almeida¹, A. Moino Junior¹, R.M. Pereira², S. Silveira Neto¹

Departamento de Entomologia-ESALQ/USP, Piracicaba, SP, Brasil - Department of Entomology and Nematology-UF. Gainesville, FL. EUA. Trabalho financiado pela FINEP - Brasil.

With the objective of finding biological alternatives to be used in the control of termites in Brazil, since 1989, the Entomology Department at ESALQ-USP has been studying the use of entomopathogenic fungi in microbial control of these insects.

Laboratory and field studies have focused on control of *Comitermes cumulans* (pasture termite) and *Heterotermes tenuis* (sugarcane subterranean termite). The basic methodology used in our studies has the objective of selecting highly pathogenic isolates to be used with several control strategies.

For control of *C. cumulans*, we have selected *B. bassiana* isolate 447 and *M. anisopliae* isolate 865. These isolates were applied in the field as an inundative introduction that caused 95 to 100% control of small to medium nests. For *H. tenuis*, from 142 *B. bassiana* isolates initially tested, 15 were selected for causing greater than 89% mortality, and among these, isolate 634 was selected as the most promising candidate. This isolate is being tested under field conditions. An inoculative introduction using a corrugated cardboard bait trap has been chosen as the application methodology. This bait trap is highly attractive to *H. tenuis*, and numbers of insects attracted reach as high as 14, 000 per unit. This fungal isolate has also been applied in combination with chemical pesticides and insect growth regulator.

21-067

COMPARISON OF THE VIRULENCE OF HYPHAL BODIES AND CONIDIA OF *VERTICILLIUM LECANII* AGAINST *FRANKLINIELLA OCCIDENTALIS* (Thysanoptera: Insecta)

G. Moritz and W. Weiward
Entwicklungsbiologie, Institut für Zoologie der Martin-Luther-Universität, Halle, Germany

The nearctic Western Flower Thrips (WFT), *Frankliniella occidentalis* (Thysanoptera), has recently become a serious pest of economic importance in Central Europe. It attacks a wide range of crops and causes damage directly through feeding, and indirectly through the transmission of plant diseases including important viruses, bacteria, and phytopathogenic fungi. The expensive commercial use of chemicals and their effects on the environment have generated an increasing interest in alternative control strategies (Moritz & Trost 1994; Schreiter et al. 1994, 1995). Moreover, most important thrips pests (WFT, *Thrips tabaci*) are difficult to control chemically and insecticide resistance occurs.

The use of *Verticillium lecanii* may help to reduce pest populations and the transmitted diseases. The host-parasite-interaction starts if the conidia or hyphal bodies (blastospores) of the fungus come into contact with the insect surface. After inoculation with either spore type, larvae and adults of the WFT show similar mortality, if immature stages are inoculated shortly after hatching or moulting (first instar larva: 71,4 h ± 8h; second instar larva: 94,7 h ± 8h). Therefore the formulation of hyphal bodies in submers or of fungal spores in emers cultures leads to an usable antagonist. Different strains of the entomopathogen and different WFT-populations show varying mortalities at subspecies level. The surface interactions let assume high or low incompatibility between the parasite and the host cuticle. For this reason the study of the autecology, ultrastructure and behavior repertoire of all ontogenetic stages after fungal infection is important.

21-068

THE EFFECT OF A NON PATHOGENIC ENDOPHYTIC FUNGUS ON THE DEVELOPMENT OF THE DIAMONDBACK MOTH *PLUTELLA XYLOSTELLA* (LEPIDOPTERA: PLUTELLIDAE)

A. Raps, S. Vidal, D. Dugassa

Institut für Pflanzenkrankheiten und Pflanzenschutz, Universität Hannover, Germany

Endophytic fungi, living within host plant tissue without causing any symptoms visible from outside, are known to occur in almost all higher plants. Although these fungi are abundant under natural conditions, research has mainly focused on endophytes-grass-relationships, and little is known about the interactions between soil-borne, root-colonizing endophytes and herbivorous insects. In our study we used the soil-borne endophyte *Acremonium alternatum* GAMS to test the hypothesis that this unspecialised fungus is able to affect the relationship between the diamondback moth *P. xylostella* and its host plant Brussels sprouts (*Brassica oleracea* var. *gemmifera*). In experiments single larvae were fed in petridishes with leaves from either treated or untreated plants. First instar larvae suffered increased mortality when fed with leaves of previously inoculated plants and developmental time was retarded. Because plant growth, leaf water, nitrogen or sugar content did not differ, we analysed secondary plant compounds which are known to be affected by fungal growth (i.e. amino acids and phytosterols). The mechanisms for altered development of the larvae will be discussed in respect to these plant metabolites.

21-069

PATHOGENICITY OF THE FUNGAL ENTOMOPATHOGEN *BEAUVERIA BASSIANA* AGAINST SUGARCANE STALKBORERS (LEPIDOPTERA: PYRALIDAE)

J. C. Legaspi, S. Wraight¹, and R. Saldaña

Texas Agricultural Experiment Station, Weslaco, TX USA -

¹ USDA-ARS-Biological Control of Pests Research Unit, Weslaco, TX USA

Pathogenicity of the fungus *Beauveria bassiana* was assessed against the Mexican Rice Borer (MRB), *Eoreuma loftini* and the sugarcane borer (SCB), *Diatraea saccharalis*. We studied the effects of a commercial formulation of dry conidia of *B. bassiana* (Mycotrol®, Mycotech Corp.) on different stages of the larval stalkborers in the laboratory. Insects were sprayed with aqueous suspensions of spores containing the wetting agent Silwet and/ or Tween at 0.01 % concentration. Each individual assay assessed the effects of wetting agent alone, low, medium and high doses of conidia. LD50 values were calculated at 5 days after treatment. LD50 values for first- and second-instar MRB were 8.9 and 10.7 spores/mm², respectively. LD50 values for first and second-instar SCB were 276.2 and 340.8 spores/mm², respectively. The mean survival time calculated for first- and second-instar MRB was 3.8 and 3.3 days, respectively. For SCB, the mean survival time of first- and second-instars was 4.7 and 4.8 days, respectively. Thus, it seems that the strain of *B. bassiana* used in Mycotrol® is more virulent to MRB than to SCB. Further studies will be conducted on the effectiveness of the fungal entomopathogen on older larval stages of MRB and SCB. Future field studies will be conducted on the effect of *B. bassiana* in susceptible and moderately resistant varieties of sugarcane.

21-070

VIRULENCE OF STRAIN 257 OF *BEAUVERIA BASSIANA* (BALS.) VUILL. TO DIFFERENT HOSTS

I. Letcheva, Sl. Draganova 1

Department of Entomology, Agricultural Institute, Plovdiv, Bulgaria-1 Institute of Plant Protection, Sofia, Bulgaria

In the report data is given about the virulence of strain 257 of *B. bassiana* (Bals.) Vuill., isolated from caterpillars of *Erannis bajaria* Schiff. to different hosts. The experiments were carried out under laboratory conditions. The insects were divided into three groups: laboratory-test-insects-larvae L2-3 of *Galleria mellonella* L., (Pyralidae: Lepidoptera) and the adult of *Acanthoscelides obtectus* Say, (Bruchidae: Coleoptera); original host - larvae L3, L4 of *Erannis bajaria* Schiff., (Geometridae: Lepidoptera); an insect from an order, different from the one of the host but included in the infectious spectrum of the pathogene - the adult of *Leptinotarsa decemlineata* Say, (Chrysomelidae: Coleoptera). Konidia and blastospores of the strain were used for the treatment. The letal time, calculated by the probit-logarithmic analysis was considered as the virulence of the strain (LT 50, LT70, LT90). It was established that the strain is specific to a certain extend, concerning its relatively higher virulency to the original host.

The larvae of *G. mellonella*, treated with konidia of the pathogene show "resistance", which we think is due to the inability of the konidia to overcome the defence of the host. The blastospores of the strain are more infectious and quickly penetrate into the body of the host. The values of the letal time (LD 90) are in confidential intervals, similar to the one of the original host. The virulence of the strain to the adults of *A. obtectus* is low. The adult of *A. obtectus* is not from the infectious spectrum of the strain 257 of *B. bassiana*.

21-071

SOME ENTOMOGENOUS SPECIES OF *PAECILOMYCES* GENUS ISOLATED IN JAPAN

K. Yaginuma

Department of Entomology, Fruit Tree Research Station Morioka Branch, Ministry of Agriculture, Forestry and Fisheries, Morioka, Japan

Isolation of *Paecilomyces* species from soil samples by using two selective media and the baiting method was attempted. Many isolates of *P. farinosus* and *P. fumosoroseus* were isolated. *P. tenuipes* was not detected by the methods. The baiting method was most effective because isolates were obtained by the method from soil samples which was not detected by two selective media. Both of the species were virulent to larva of peach fruit moth, *Carposina sasakii* (= *C. niponensis*) which was a key pest of Apple, Japanese pear and peach in Japan.

Four isolates of *Paecilomyces* species were isolated from soil samples collected in Oota, Okinawa, Hiroshima and Tokyo by using the baiting method. They were characterized by their cylindrical and large conidia (8-11x2-3 μ m). They were pathogenic to larvae of peach fruit moth. In 1994, pupae of cicada, *Meimura oalifera* infected with a fungus were collected in Ibaraki. Synnemata erected from head of cicada were 3.5-5 cm and powdery near apex due to the conidial mass. These isolates were resemble closely to them from soil samples. Both of isolates isolated from soil and cicada were identified as *P. cicadae*. It was found that this species was also virulent to lepidopteran insect.

In 1995, *P. amoeneroseus* was isolated in Morioka where was located in the northern part of Japan and was found to be pathogenic to lepidopteran and coleopteran insects.

QUICK AND LASTING CONTROL EFFECT FROM THE APPLICATION OF *VERTICILLIUM LECANII* (ZIMMERMAN) (HYPHOMYCETALES: MONILIACEAE) PLUS SILWET® L-7607N ON *MYZUS PERSICAE* (SULZER) (HEMIPTERA: APHIDIDAE)

S. Tsuchiya, T. Imai, T. Matsuki, T. Fujimori

Applied Plant Research Laboratory, Yokohama Center, Japan Tobacco Inc., Aoba-ku Yokohama, Japan

The use of the entomopathogenic fungus, *Verticillium lecanii* (Zimmerman), as a pest control agent, has attracted applied entomologists' attention because of their low human toxicity and environmental friendliness. However, the application of *V. lecanii* is not expected to produce sufficient control of rapidly reproducible pests such as aphids when their density is high, perhaps owing to its slow action: The reproduction of such pests generally exceeds the outbreak of the disease. In order to improve such a situation, we examined the use of surfactants that exhibit quick aphicidity¹ together with *V. lecanii*. The germination of the blastospores was little suppressed when two 0.1% silicone surfactants were applied: The germination rates were 83.2% and 95.2% in Silwet® L-7607N and L-77 solutions, respectively. The combined application of Silwet® L-7607N and the blastospores on *Myzus persicae* (Sulzer) well met our expectations: the spray of the suspension mixture that contained the blastospores (1.0×10^7 CFU/mL), Silwet® L-7607N (0.1%), and sodium carboxymethyl cellulose (0.1%) over approximately 8-leaf-stage *Nicotiana tabacum* (L.) produced immediate and lasting control effect at 18.9°C and 95.8% RH in averages, whereas the spray of the suspension without the surfactant did not show any aphicidity within 3 days after treatment under the same condition. These results suggest that the application of a silicone surfactant together with *V. lecanii* would produce sufficient control on aphids regardless of their initial density.

DISEASES OF GREYBACK CANEGRUB (COLEOPTERA: SCARABAEIDAE) IN SUGARCANE IN AUSTRALIA

L.N. Robertson, D.J. Dall¹, J. Lai-Fook¹ and P.W. Walker²

Bureau of Sugar Experiment Stations, Dallachy Road, Tully, Queensland, Australia - 1 CSIRO Division of Entomology, Clunies Ross Street, Canberra, Australia -2 BSES, Brandon, Queensland, Australia.

The melolonthine scarab *Dermolepida albohirtum* (Waterhouse) is the most damaging of the insect pests of sugarcane in Australia. The root-feeding larvae, known as greyback cane-grubs, are difficult to control because they develop in well-grown cane crops which are inaccessible to conventional pesticide application machinery.

Disease incidence was determined during a study of the population dynamics of greyback cane-grub in North Queensland, Australia. The fungus, *Metarhizium anisopliae*, accounted for 31% of cane-grubs which died across all sites. The protozoan *Adelina* sp. had its highest incidence (100%) in cane-grubs which died from Stone River near Ingham in 1994. Seventy-four percent of grubs collected from this site died in the laboratory. Cane-grub population density declined by approximately 80% at Stone River during the 1994 season. Localities with low incidence of *Adelina* in cane-grubs showed little change in population density throughout the season. *Adelina* sp. was also recorded from adult greyback cane-grub.

Other diseases recorded from field-collected cane-grubs included an entomopox virus, bacteria (*Bacillus popilliae* and *Bacillus* nr. *sphaericus*), and a microsporidian resembling *Nosema*. "*Nosema*" sp. was experimentally transmitted to healthy cane-grubs, causing retarded growth and eventual death.

We postulate that the cyclical pattern of outbreaks of greyback cane-grub recorded every 10 - 15 years throughout North Queensland may be caused by variations in the incidence of entomopathogenic diseases. *Adelina* infection, in particular, may influence population dynamics of greyback cane-grub.

21-073

INTERACTIONS BETWEEN A NON-PATHOGENIC FUNGUS, *ASPERGILLUS NIDULANS*, AN ENTOMOPATHOGENIC FUNGUS, *BEAUVERIA BASSIANA* AND THE INSECTS *DYSDERCUS PERUVIANUS* (HEMIPTERA: PYRRHOCORIDAE) AND *SPODOPTERA FRUGIPERDA* (LEPIDOPTERA), RESPECTIVELY.

B. Sandskär, T.M.A.D. Zucchi, S. Daffre

Department of Parasitology, ICB II, University of São Paulo, São Paulo, Brasil.

The insects were inoculated with the conidia-containing solutions, in order to study their immune response and to investigate possibilities of biological control.

D. peruvianus were inoculated with a Hamilton syringe, in volumes of 2-4 µl (3.2×10^7 conidia/ml). The insects were kept for five days after treatment. The mortality was recorded. Hemolymph was tapped from the hind leg, mixed with saline and plated on selective media. A reduction of the number of the conidia was noted (60-80%). Classic genetic experiments were performed with the survivors of the UT 196 strain in crosses to normal strain. The genotypical analyses indicate that inside the insect occurred several changes in the genome of the fungus affecting their genes expression and meiotic pattern. This was also evidenced by treating conidia with demethylation agent such as 5-azacytidine.

The mortality was not elevated for *A. nidulans* while the tested isolate of *B. bassiana* was highly pathogenic.

Both, *in vitro* and *in vivo* tests with *S. frugiperda*, gave similar results.

*Support CNPq and FAPESP.

21-075

SYNERGISTIC EFFECT OF AN ENTOMOPATHOGENIC FUNGUS (*METARHIZIUM ANISOPLIAE*) WITH CHEMICAL INSECTISIDES AGAINST SCARAB LARVAE.

H. Hiromori, J. Nishigaki

Faculty of Agriculture, Shizuoka University, Ohya, Shizuoka 422, Japan

An entomopathogenic fungus *M. anisopliae* had not showned the sufficient control effect against soil inhabiting insects such as larvae of scarab beetles by using this fungus singly. In this experiment, we investigated the synergistic action of *M. anisopliae* with several chemical insecticides against scarab larvae.

In the laboratory test, higher mortality effect was obtained by treating conidial suspension of *M. anisopliae* with few doses of insecticides against scarab larvae. In these application, we observed that the larval dead bodies were almost infected with *M. anisopliae*. Hence, it is assumed that the use of *M. anisopliae* with chemical insecticides against scarab larvae will be much effective and take on a important role in the system of IPM.

21-076

SPRAYABLE GRANULE FORMULATIONS FOR *BACILLUS THURINGIENSIS*P. Tamez-Guerra¹, M.R. McGuire², H. Medrano-Roldan³, L.J. Galan-Wong¹, F.E. Vega².¹Departamento de Microbiología e Inmunología, Universidad Autónoma de Nuevo León, Monterrey, Mexico; ²USDA-ARS, Bioactive Agents Research Unit, Peoria, IL, USA; ³Instituto Tecnológico de Durango, Durango, Mexico

Formulations incorporating modified starches and flours were developed for extending the residual activity of *Bacillus thuringiensis* (Bt). The basic formulation contained nixtamalized flour from corn (commonly used in Mexico for industrial purposes), cornstarch, corn oil, lactic acid, alcohol, and sugar. When mixed with water and active ingredient and spray dried, small granules were formed. These granules could then be added to a spray tank and sprayed onto a target. Variations of these ingredients included substituting the nixtamalized flour with pregelatinized flours or starches commonly available in the U.S. Tests were conducted in the laboratory to determine insecticidal activity of Bt and resistance to simulated environmental factors. In diet incorporation tests against three insect species, formulated Bt killed as many or more larvae than unformulated Bt suggesting that the ingredients and processing did not harm the activity. In many cases, activity was increased perhaps due to the feeding stimulant property of the formulation. Cotton leaf surfaces were treated with the formulations and exposed to full simulated sunlight delivered by a Suntest CPS (Heraeus) for 8 h. Unformulated Bt routinely lost about 50% activity during this exposure; however, Bt formulated in nixtamalized flour retained 90-95% activity. There was a reduction of solar stability as the amount of Bt increased in the formulation. We believe these formulations offer a viable, microencapsulated system utilizing surplus, natural materials. Funded in part by CONACYT ref. 3559-N9311.

21-078

DEVELOPMENT OF FOUR CELL LINES FROM THE COLORADO POTATO BEETLE, *LEPTINOTARSA DECEMLINEATA* (SAY) (COLEOPTERA: CHRYSOMELIDAE), THEIR CHARACTERIZATION, AND THEIR USE FOR STUDY AND DOSAGE OF ENTOMOPATHOGENS.G. Charpentier¹, S. Bellonci², L. Tian¹.¹ Département de Chimie-biologie, Université du Québec à Trois-Rivières, C.P. 500, Trois-Rivières, Québec, Canada, G9A 5H7. ² Centre de Recherche en Virologie, Institut Armand-Frappier, C.P. 100, Laval-des-Rapides, Québec, Canada, H7V 1B7

Colorado potato beetle is an economically important pest. In order to isolate new pathogens (viruses, microsporidia, etc...) or to evaluate the potency of some pathogens (serovarieties and mutants of *Bacillus thuringiensis*, fungi, etc...) for their control, we established four cell lines from Colorado potato beetle. One cell line was initiated in the M3 medium supplemented with 20% fetal bovine serum (FBS) from embryonated eggs collected from field or in our laboratory colony. It has been transferred after some passages in Ex-Cell 400 medium + 20% FBS. One other cell line was started from hemocytes of larvae in Ex-Cell 400 + 5% FBS. Finally, two other cell lines were started from hemocytes of adults; one in Ex-Cell 400 + 20% FBS and 1% of lipid mixture and the other with 5% FBS only. These cell lines have been characterized by their morphology in light and electron microscopy, their karyotypes and measurement of cell growth. Isozyme analysis are now in progress. Each cell line differed in morphological, karyotypical and growth patterns. The cell line started from embryonated eggs was growing slower than the others. Cytotoxicity of solubilized crystal delta-endotoxins from different *Bacillus thuringiensis* formulations (M-one, Trident, MYX-1806, Teknar HPD, and Thuricide) was tested on these cell lines. Our Colorado potato beetle cell lines are sensitive to the solubilized toxins of some strains of *B. thuringiensis* (serovarieties *San Diego* and *tenebrionis*). We also tested the cytotoxicity of destruxins from *Metarhizium anisopliae* (an entomopathogenic fungi) on these cell lines. We are now evaluating the permissivity of these cell lines for some entomoviruses.

COMPUTERIZED ECOLOGICAL DATABASE OF THE WORLD'S INSECT PATHOGENS

D. W. Onstad¹, R. Giordano², J. I. R. Larsson³¹Center for Economic Entomology, Illinois Natural History Survey, Champaign, IL USA, ²Dept. of Entomology, University of Illinois, Urbana, IL USA, ³Dept. of Zoology, Lund University, Lund, Sweden

There is a need for insect pathologists, ecologists, and government regulators to better understand the ecology of pathogens and their hosts. Can we predict the host-specificity or host range of a pathogen? This database can help regulators and decision makers involved in biological control assess the risk of introduced pathogens harming beneficial and endangered insect species. The database can also be used to find out what species have been observed infecting pests.

The types of information entered into the insect pathogen database include: insect species, family, and order; pathogen species, two higher taxa, and group (i.e. bacteria, fungus, microsporidia, protozoa, virus); life stage of insect susceptible to infection; host tissue infected; intermediate host; habitat of insect host; plants or animals on which the insect host feeds; number of host generations per year; whether the insect/pathogen association was observed in the field or the laboratory; the country in which the insect/pathogen association was observed; the name(s) of the observer or the reference in which the insect/pathogen association was cited.

The database has over 4,000 associations between species of pathogen and species of insect, mite or tick. In 1996 it will be accessible on the World Wide Web.

THE BACTERICIDAL EFFECT OF ANTIBACTERIAL PEPTIDE FROM CHINESE OAK SILKWORM TO THE PATHOGEN OF BACTERIAL ULCER AND YELLOW SHOOT DISEASES IN CITRUS

Q • J • Zhang, J • N • Zhang, Z • R • Huang, S • C • Tan, Z • Y • Guo

South China Agricultural University, Guangzhou, P • R • China, 510642-1 South China Normal University, Guangzhou, P • R • China, 510630-2

In this article, the bactericidal effect of antibacterial peptide (AP) from Chinese oak silkworm pupae, *Antheraea pernyi* on the growth of the pathogens of bacterial ulcer (*Xanthomonas campestris* PV *citri*) and yellow shoot disease (Bacterium like Organism, BLO) was firstly reported.

The inducible AP was immunized from the haemolymph of Chinese oak silkworm pupae by injecting with *E. coli* K12D31. The AP was purified by boiling (100°C, 30min), centrifuging and separating with Sephadex G-50. The purified AP was labelled with fluorescein yellow.

Both pathogens were treated with 10µg/ml of AP. The optimal effective time was 20-60 min for killing the bacteria. Observation under the laser scanning confocal microscopy and electron scanning microscopy showed that the primary targets of AP were the cell membrane. In the initial action stage, the receptor sites were seriously injured and some small channels were found on the cell surface, then the intracellular substances were pressed out of the cell, at last the cells became empty and died.

MICRO AND MACRO ORGANISMS OF WILD APIDAE ADULTS IN SOUTHERN ITALY.

O. Triggiani, E. Tarasco

Istituto di Entomologia agraria, Università di Bari, Italy

The research carried out in the Apulian Region (Southern Italy) during 1988-1995 pointed out the presence of micro and macro organisms in *Bombus* spp., *Psithyrus* spp., *Xylocopa violacea* L., *Andrena carbonaria* L., *Halictus brunnescens* Eversmann and *H. fulvipes* Klug adults. The following Protozoa were isolated in *Bombus* and *Psithyrus*:

-*Apicystis* (= *Mattesia*) *bombi* (Liu, Macfarlane & Pengelly), reported for the first time in Italy in 1988, was more frequently found in *Bombus terrestris* L. during July 1995 (32%), alone or associated with *Nosema bombi* and *Critidia bombi*.

-*Nosema bombi* Fantham et Porter, constantly isolated from *B. terrestris*, *Megabombus pascuorum* Scopoli, *Psithyrus vestalis* Geoffr., was more frequent in anthropized biotopes and experimental fields.

-*Critidia bombi* sp. n. was primarily found in the gut of *B. terrestris*, *M. pascuorum*, *Megabombus hortorum* L., *Megabombus ruderatus* Fab., *Pyrobombus sicheli* Rad. Heavily infected adults had problems in flying.

The Nematode *Sphaerularia bombi* Dufour was isolated from *B. terrestris*, *M. pascuorum*, *P. sicheli* and *M. ruderatus* queens that were parasitized up to 80%. Juvenile stages of *S. bombi* were also found in two workers of *P. sicheli* in May 1994 and in two workers of *B. terrestris* in April 1995.

Up to four queens of *B. terrestris* proved to be parasitized by *Syntrenus* sp. (Hymenoptera: Braconidae) during May 1990-93 and 1995. A percentage ranging between 3.0% and 75% of males, workers and seldom queens of *Bombus* was parasitized by the Diptera *Conops flavipes* De G. Different species of Protozoa, not yet identified, were found in other Apidae during 1994-95. A *Critidia* sp., in only a male out of 7 collected in March 1994, and a Gregarine *Leydyana* sp., in one sample collected in September 1994 in the Pollino National Park, were found in *Xylocopa violacea*. Different species of Gregarines were isolated from *Andrena carbonaria*, *Halictus brunnescens* and *H. fulvipes*. In both species of *Halictus* the Gregarines were present in 90%-95% of the specimens during September 1995.

21-082

Observations on *Bacillus thuringiensis* toxicity against *Ceratitis capitata* Wied. (Dipt. Tephritidae)

E. Bazzoni¹, G. Delrio¹, M. Mura², S. Rubino¹, A. Satta³, R. Prota¹

1. Ist. Ric. Controllo Biologico Ambiente - CNR Sassari, Italy -

2. Ist. Microbiologia e Virologia - Università di Sassari, Italy -

3. Istituto di Entomologia agraria - Univ. Sassari, Italy -

The medfly (*Ceratitis capitata* Wied.) is considered of great economic importance in the Mediterranean area, since it attacks a variety of fruits. Control of this pest is based on cover sprays with organophosphorous insecticides or on bait sprays with protein hydrolyzate, that have detrimental effects on beneficial entomofauna and cause environmental problems. The development of a safe biocontrol agent to replace organophosphorous insecticides in bait sprays technique would solve these problems.

For this purpose, we have obtained from about 100 samples of soil, collected in two Mediterranean islands (Sardinia and Corsica) and in Africa (Angola and Zimbabwe), 70 isolates of Bt with typical parasporal crystal inclusions of different sizes and shapes.

Preliminary bioassays of Bt against a laboratory population of larvae and adults of *C. capitata*, showed a high variability of toxicity correlated to the isolates and to the insect life stage. The larvae were more susceptible than adults to the same Bt suspension and the effect was dose-dependent. At very low doses the development of the larvae was delayed. In some case, with a dose of 1.3×10^9 spores and crystals per gram of larval diet, 100% of mortality was reached.

The adult fly showed a remarkable higher level of resistance compared to the larvae, reaching a maximum peak of mortality of 40%.

Some isolates of Bt were active only on larvae or on adults.

21-081

EFFECT OF STRESS ON THE SUSCEPTIBILITY OF INSECTS TO PATHOGENS

T.H. Schuler¹ & H.F. van Emden

School of Plant Sciences, The University of Reading, United Kingdom

Especially in relation to insect cultures, it is frequently stated that stress increases susceptibility of insects to diseases. However, a search of the literature gave little support for such a general statement. Two pest insects, the rose-grain aphid *Metopolophium dirhodum* and the diamondback moth *Plutella xylostella*, were therefore subjected to various stress treatments.

Rose-grain aphids were sprayed with sublethal concentrations of the pyrethroid insecticide cypermethrin or reared on a resistant wheat cultivar before being infected with the hyphomycete fungus *Verticillium lecanii*. None of these two stress treatments resulted in a consistently higher mortality of stressed aphids from fungus compared to nonstressed aphids.

Stress caused by cypermethrin or by the botanical insecticide azadirachtin also failed to increase the susceptibility of larvae of the diamondback moth to the bacterial pathogen *Bacillus thuringiensis*. On the other hand, some resistant host plants were found to increase *B. thuringiensis*-related mortality in *P. xylostella*.

It has to be concluded that stress as a general phenomenon does not necessarily increase the susceptibility of insects to diseases but that individual stress factors, such as host plant resistance, can have an effect and should be considered in integrated pest management systems.

21-083

PATHOGENICITY OF *BACILLUS THURINGIENSIS* VAR. *KURSTAKI* AGAINST *SPILOSOMA OBLIQUA* (W)

M. A. Haque

Department of Entomology, Bangladesh Agricultural University, Mymensingh 2202, Bangladesh.

Jute hairy caterpillar *Spilosoma obliqua* (W), a serious pest of jute crop, also attacks a number of other crops such as cotton, groundnut, brinjal, cabbage, cauliflower, soybean, mashkalai etc. To overcome the adverse effects of synthetic pesticides in agroecosystem, use of microbial pathogens particularly bacterial pathogen can play a significant role in this regard. Because bacterial pathogens are safe, selective and compatible with most pest control options of integrated pest management. The pathogenicity (LC₅₀, LC₉₀, LT₅₀, LT₉₀ values) of the bacterial pathogen, *Bacillus thuringiensis* var. *kurstaki* was determined against different instars of *S. obliqua*. The effect of the pathogen on the growth and development of the insect pest was also studied. *B. thuringiensis* could be an alternative of synthetic pesticides for the management of *S. obliqua*.

21-084

EXPRESSION OF *BACILLUS THURINGIENSIS* INSECTICIDAL CRYSTAL PROTEIN FRAGMENTS ENGINEERED INTO COMMERCIAL WALNUTS (*JUGLANS REGIA* L.)

P.V. Vail¹, J.S. Tebbets¹, A.M. Dandekar², G.H. McGranahan², C. Leslie², S.L. Uratsu²

1 USDA, ARS, Horticultural Crops Research Laboratory, Fresno, CA USA - 2 Department of Pomology, University of California, Davis, CA USA

In 1989 studies began to incorporate the genes responsible for the production of *Bacillus thuringiensis* insecticidal crystal protein fragments (ICPFs) into the genome of walnut. If successful, the research could have impact on both production and postharvest insect control methods. Initial studies with the purified ICPFs were conducted to determine the susceptibility of three important production/storage pests, navel orangeworm (*Amyelois transitella*), codling moth (*Cydia pomonella*), and Indianmeal moth (*Plodia interpunctella*) of commercial walnuts to two ICPFs (CryIA(b) and CryIA(c)). Both proteins were toxic to the insects. *A. transitella* was the least and *P. interpunctella* the most susceptible species. ICPFs slowed *A. transitella* development but few other sublethal effects were noted. Transgenic walnut embryos known to contain ICPF genes based on initial screenings by GUS, kanamycin resistance and/or southern blot were fed to *C. pomonella* or *A. transitella* larvae. If significant mortality could be obtained with these species toxicity to *P. interpunctella* would likely be assured. Early presumptive engineered embryos proved to have little activity towards the subject pests indicating expression problems. With later constructs we have obtained a number of embryo lines expressing varying levels of ICPFs. The embryos screened had low, medium, and high levels of expression. Feeding on high expression embryos was minimal. Walnut seedlings from embryos with high levels of expression were planted in 1995.

21-086

DIFFERENCE OF ANTIBACTERIAL ACTIVITY INDUCIBLE IN THE HEMOLYMPH AMONG THE SILKWORM, *BOMBYX MORI*, RACES BY IMMUNIZATION (LEPIDOPTERA:BOMBYCIDAE)

E. Okada, K.Mase, T. Yamamoto

Research Team of Silkworm Breeding, National Institute of Sericultural and Entomological Science (NISES), Matsumoto Nagano, Japan

To know a concern of antibacterial activity with differences of healthiness among the silkworm races, antibacterial assay by measuring of bacterial growth inhibition was examined. The respective hemolymph were collected from 10 races of silkworm (4 of chinese, 3 of japanese, 2 of european strains and 1 of hybrid) with injection of dead bacteria and were used.

These activities were found to differ respectively. DAIZO (a chinese strain)'s activity was especially higher than the others while its overall hemolymph proteins concentration was the lowest.

21-085

ANTAGONISTIC EFFECT OF Cry1Ac AND Cyt1A TOXINS OF *Bacillus thuringiensis* ON *Trichoplusia ni* (Hübner) (LEPIDOPTERA: NOCTUIDAE) LARVAE AND TN5B1-4 CELLS.

M.C. Del Rincón-Castro, J.E. López-Meza, J. Barajas-Huerta, and J.E. Ibarra, Depto. de Biotecnología y Bioquímica, CINVESTAV-IPN, Irapuato, Gto. MÉXICO.

Most of the *Bacillus thuringiensis* (*Bt*) strains show a set of different protoxins in their parasporal crystals. Some of these combinations clearly interact synergistically, like the toxins present in *Bt israelensis*. Synergism in other combinations is only speculative. This report introduces a novel joint action between toxins from significantly different strains. A series of *per os* bioassays against late 1st instar larvae of the cabbage looper, *Trichoplusia ni*, was conducted in order to estimate LC₅₀s of pure Cry1Ac crystals from *Bt kurstaki*, pure Cyt1A crystals from *Bt israelensis*, and two different combinations of both toxins. The first LC₅₀ was estimated at 2.46 ng/cm² diet, while Cyt1A crystals showed no toxicity, even at very high doses. LC₅₀s were estimated at 15.69 and 19.05 ng Cry1Ac crystals per cm² diet, when mixed with 100 and 1,000 ng Cyt1A crystals per cm² diet, respectively. *In vitro* bioassays of pure, trypsin activated toxins against Tn5B1-4 cells of *T. ni*, showed contrasting susceptibility. LC₅₀s were estimated at 4,967 and 11.69 ng/ml medium of Cry1Ac and Cyt1A crystals, respectively. When mixtures of toxins were assayed using different proportions, eight different LC₅₀s were estimated. All of them were significantly higher when compared to the expected LC₅₀s of the mixtures. This results indicate an obvious antagonism between toxins, both, *in vivo* and *in vitro*. These are the first evidences of a novel joint effect of *Bt* toxins from different strains. Various possible explanations on this relationship are discussed.

21-087

EFFECT OF *BACILLUS THURINGIENSIS* VAR. *KURSTAKI* δ -ENDOTOXIN ON INSECT FAT BODY STRUCTURE

Hyang-Mi Cheon, Ja-Hyang Cho¹, Hong-Ja Kim, Seok-Kwon Kang², Sook-Jae Seo

Department of Biology, College of Natural Science, Gyeongsang National University - 1 Department of Pathology, Hospital of Gyeongsang National University, Chinju 660-701 - 2 Department of Agriculture Biology, College of Agriculture and Life Sciences, Seoul National University, Suwon 441-744, Korea

The effect of *Bacillus thuringiensis* var. *kurstaki* HD-1 δ -endotoxin was determined on the structure and function in isolated fat body tissue from fall webworm, *Hyphantria cunea* Drury. Protein synthesis and toxin-binding experiment were performed by autoradiography, immunocytochemistry, and scanning electron microscopy.

After fat body exposure to 62KDa endotoxin over 150 μ g/ml, protein synthesis was completely inhibited. Immunostaining was observed 30min after *in vitro* fat body exposure to toxin. By 1h after exposure, high degree of staining is observed along the fat body membrane, resulting in separation of basal lamina from fat body and cell disruption. After 2h cellular damage had increased, with protrusion of cytoplasmic contents as well as cell decay.

21-088

EFFECT OF *Bacillus thuringiensis* and INSECT GROWTH REGULATOR ON THE CONTROL OF THE DIAMOND BACK MOTH, *Plutella xylostella* (L., 1758) (LEPIDOPTERA: PLUTELLIDAE), IN CABBAGE.

G. Papa¹, F.V. Siqueiri¹, G. Verga¹

1- Department of Biology, UNESP, Ilha Solteira/SP, Brazil

The control of *Plutella xylostella* in cabbage using conventional insecticides is a serious problem all over the world. The purpose of the experiment was to be study the effect of *Bacillus thuringiensis* var. Aisawai (AGREE WP) and insect growth regulator (Chlorfluazuron 5% EC) as alternative of control of *P. xylostella*, under field conditions, in São Paulo State/Brazil, during 1993. The defoliation and the quantity of marketable standard cabbage head were evaluated, after 5 weekly applications of *B. thuringiensis* (rates: 750, 1000 and 1500 g c.p./ha), Chlorfluazuron 5% EC (rates: 400 and 600 ml c.p./ha) and Permethrin 38,4% EC (rate: 696 ml c.p./ha). The treatments were distributed in random blocks, with 4 replications. Each plot consisted of 40 plants. The cultivar utilized was Matsukaze.

The results showed that *B. thuringiensis* (rates: 750, 1000 and 1500 g c.p./ha), Chlorfluazuron 5% EC (rates: 400 and 600 ml c.p./ha) obtained 88, 94, 100, 95 and 96% of marketable standard cabbage head, respectively, showing that treatments may be used in Integrated pest management programs. The treatment with pyrethroid insecticide, Permethrin 35,4% EC (rate: 696 ml c.p./ha), obtained just 12% of marketable standard cabbage head. The control treatment (without applications) showed severe attack by *P. xylostella*, whereas all the cabbage head produced were below the market standard.

ENTOMOPATHOGENIC FUNGI DEGRADE EPICUTICULAR HYDROCARBONS OF *TRIATOMA INFESTANS* (HEMIPTERA: REDUVIIDAE)

M. P. Juárez, R. Napolitano

Instituto de Investigaciones Bioquímicas de La Plata. Facultad de Ciencias Médicas- UNLP- calle 60 y 120 (1900) La Plata - Argentina - Fax #: 54 21 25 8988 - e-mail: mjuarez@isis.unlp.edu.ar

The role of insect cuticular hydrocarbons as a barrier against water loss, agrochemical and toxic penetration has been frequently addressed.

Because nearly all fungal infections are produced by invasion through the host's cuticle, this organ is also the primary defense against microbial diseases.

In this paper we analyze the ability of entomopathogenic fungi to utilize insect epicuticular hydrocarbons. Strains of *B. bassiana* and *M. anisopliae* were grown on synthetic hydrocarbon enriched media as the only carbon source. Similar experiments were performed with hydrocarbons or non-hydrocarbon lipid fractions extracted from the blood-sucking insect *T. infestans*.

Conidia production was significantly higher in media containing cuticular hydrocarbons rather than other cuticular lipid fractions or synthetic hydrocarbons.

Fungal hydrocarbon composition is modified when grown in a hydrocarbon enriched media as shown by gas-chromatography analyses.

Hydrocarbon consumption was measured using synthetic radioactive hydrocarbon. The degradation products were free fatty acids, polar lipids and acylglycerols as shown by radio-thin layer chromatography and radio-high pressure liquid chromatography analyses.

21-089

BINDING OF *BACILLUS THURINGIENSIS* INSECTICIDAL CRYSTAL PROTEINS TO THE MIDGUT OF *HELICOVERPA ARMIGERA* (HÜBNER) (LEPIDOPTERA: NOCTUIDAE)

Liao Chunyan, S.C. Trowell and R.J. Akhurst

CSIRO Division of Entomology, Canberra, Australia

A key step in the toxic action of *Bacillus thuringiensis* insecticidal crystal proteins (ICP) is the binding of the activated toxin to the midgut epithelium. Changes in the affinity and/or concentration of the binding site have been identified as a basis for resistance to Bt.

As part of a project on resistance to CryIAC, the ICP produced in transgenic cotton, by *Helicoverpa armigera* we determined the toxicity of various ICPs for *H. armigera* and found that there were only a few ICPs that were sufficiently toxic to be useful alternatives to CryIAC in resistance management. Relative affinity of the *H. armigera*-toxic ICPs and CryIAC for a midgut binding site was determined by competitive binding assays.

A CryIAC binding protein was purified from *H. armigera* midgut epithelium on a CryIAC affinity column and characterised.

21-091

TACTICS OF THE MICROBIOLOGICAL PROTECTION OF VINEYARDS FROM LEPIDOPTERA PEST INSECTS

I. Malania, G. Chkhubianishvili¹

Laboratory of Microbiological Control, Kanchaveli Georgian Research Institute of Plant Protection, Tbilisi, Republic of Georgia, - 1 Same

Among the Lepidoptera insects the grape berry moth, *Lobesia botrana* Den. & Schiff. (Tortricidae) is one of the important pest of vineyards in Georgia. On the early grape vine sort - "Tbilisuri" - this pest has been developed in two generations. The first damages flower cluster, second - the ripe berries. The scheme of the microbiological protection of "Tbilisuri" has been developed: one treatment before the completing of flowering and two - during the riping of grape. The same pest on the production grape vine sorts developed in three generations, where the larvae of second and third generations are more harmful. The bacterial preparations on the base of *Bacillus thuringiensis* are used both early and industry grape vine sorts from the grape berry moth and other species of *Lepidoptera* insects in the main regions of viticulture of Georgia.

21-092

MANAGEMENT OF DIAMONDBACK MOTH, *PLUTELLA* *XYLOSTELLA*, USING BIOLOGICAL INSECTICIDES

Abstract. Several studies were conducted to control diamondback moth (DBM), *Plutella xylostella* (L.), on cabbage (*Brassicae oleracea* var. *capitata* L.) using conventional, biological and botanical insecticides in Tropical Research and Education Center, Homestead, Florida, USA. Emamectin benzoate alone or in rotation with Dipel 2x (1.0 lb./A) or Xentari (1.0 lb./A) significantly reduced *P. xylostella* populations. In the second test, all formulations of *B. thuringiensis* (ABG 6347, Dipel 2x, San 415 & 420, Agree, Able, & Agree in combination with Able) significantly reduced *P. xylostella* populations. In the third study, significantly lowest number of *P. xylostella* larvae was recorded on Xentari treated plants. Other *B. thuringiensis* formulations (Crymax, Agree Dipel 2X, LoCh, & Biobit) also reduced *P. xylostella* larvae when compared with the nontreated control. In the fourth test, *Anagrapha falcifera* (AfNPV) virus performance was comparable with different *B. thuringiensis* formulations (Able, Agree in combination with Able, Xentari, Crymax, & Biobit HP) in controlling diamondback moth. Neemix and Regent also significantly reduced this pest. In the fifth test, different formulations of Azadirachtin significantly increased marketability of cabbage by controlling *P. xylostella* larvae. This information is useful to manage diamondback moth populations in commercial fields using various insecticides in rotation.

21-094

ACTIVITY OF SOME STRAINS OF *BACILLUS THURINGIENSIS* AGAINST CORN BORERS IN EGYPT

M. Hafez, H.S. Salama, A. El-Moursy
and A. Abdel Rahman

Faculty of Science, Cairo University
& National Research Centre, Dokki, Cairo

Studies have been carried out on the effect of the microbial control agent *Bacillus thuringiensis* on the two lepidopterous corn borers *Chilo agamemnon* and *Ostrinia nubilalis* which are considered as major agricultural pests in Egypt. The potential activity of some strains of *B. thuringiensis* was evaluated against the second instar larvae of the two corn borer species. Data on the LC₅₀, slopes, 95% confidence limits and potencies of the tested varieties were determined. With respect to *O. nubilalis*, the data indicate that Dipel 2X (*Bacillus thuringiensis* var. *kurstaki* HD-1) is the most potent. The LC₅₀ for Dipel 2X was 2.68 ug/gm diet. The LC₅₀ for other strains ranged between 3.12 and 31.95 ug/gm. In the case of *C. agamemnon*, the lowest LC₅₀ was also recorded with Dipel 2X being 3.68 ug/gm diet. Concerning other tested strains, the LC₅₀ ranged between 6.21 - 15.11 ug/gm. The results generally show that Dipel 2X (*B. thuringiensis* var. *kurstaki* HD-1) is the most potent against the two tested species, as compared to the standard.

NATURALIS™: A BIOPESTICIDE (*BEAUVERIA BASSIANA* JW-1) FOR CONTROL OF ECONOMIC INSECTS IN FIELD CROPS, VEGETABLES, ORNAMENTALS, AND GREENHOUSES WITH EMPHASIS ON CONTROL OF *BEMISIA*

James E. Wright

Troy Biosciences Inc., Phoenix, Arizona, USA 85009

Naturalis™ is a natural biological control product that has activity against major pests of cotton, vegetables, and ornamentals. The active ingredient, an insect specific fungus, is contained in the patented product which is registered by EPA in the United States and other countries. The Greenhouse Growers Association in the U.S. named Naturalis as the number one product for 1996 for use against insects, particularly *Bemisia*, thrips, and aphids. Laboratory and field evaluations have established that Naturalis is highly compatible with natural predators and parasites, i.e., *Chrysoperla* sp., *Eretmocerus* sp., *Encarsia* sp., *Scymus* sp. and others. Results of U.S. and international field trials in field crops, vegetables, ornamentals, and greenhouses will be presented.

21-095

CONTROL OF PLUM CURCULIO ADULTS WITH *STEINERNEMA CARPOCAPSAE*

G. Chouinard, G. Bélair¹, C. Vincent¹

Service de Phytotechnie de St-Hyacinthe, Direction de la Recherche et du Développement en Agro-alimentaire, Ministère de l'Agriculture, des Pêcheries et de l'Alimentation du Québec, Saint-Hyacinthe, Canada -
¹ Horticultural Research and Development Center, Agriculture and Agri-Food Canada, Saint-Jean-sur-Richelieu, Canada

The entomopathogenic nematode *Steinernema carpocapsae* All strain was evaluated for field effectiveness against adult plum curculio, *Conotrachelus nemuphar* Herbst, a key apple pest in Quebec apple orchards. In a first experiment, the persistence of *S. carpocapsae* on leaves, flower clusters and twigs was monitored using bioassays with *Galleria mellonella* larvae. In 1992, 1993, 1994 and 1995, *S. carpocapsae* juveniles remained infective on apple leaves 38, 42, 98 and 24 h after application respectively. In bioassays, the percentage of *G. mellonella* mortality was consistently higher on leaves, intermediate on flower clusters and lower on twigs for all application dates. After a 12 and 24 h exposure period, the survival rate of *S. carpocapsae* on leaves was estimated at 35 and 15% in 1994 and at 87 and 0% in 1995 respectively. In a second experiment in 1993 and 1994, three consecutive border row sprays of *S. carpocapsae* were applied with a hand gun sprayer to the foliage and the ground of an insecticide-free orchard against *C. nemuphar* adults. Plum curculio damage at harvest reached 5% the first year and 55% the second year, as compared to 80 and 85% in an adjacent insecticide-free orchard, and 0.0 and 0.5% in another adjacent orchard protected with chemical insecticides. In a third experiment performed in 1994, multiple broadcast sprays of *S. carpocapsae* applied with an orchard sprayer at 200 PSI showed no significant effectiveness on fruit damage caused by *C. nemuphar*. In a fourth experiment performed in 1993 and 1995, nematode suspensions applied at the base of tree trunks significantly reduced by 82 and 100% respectively the survival of plum curculio adults maintained within this habitat over a 7 day period. *G. mellonella* mortality from bioassays performed on nematode treated soil samples averaged 100, 75 and 40% after 4, 7 and 10 days respectively.

Integrated Pest Management

22-001

INTRODUCTION: IPM, APPLYING PRINCIPLES OF COMMUNITY ECOLOGY

M. W. Brown

Appalachian Fruit Research Station, U. S. Dept. Agriculture, Agricultural Research Service, Kearneysville, WV, USA

IPM has been successful in reducing the input of pesticides while maintaining production of high quality fruit. Further reductions in pesticide will come in the future with refinements in methodology, but such advances will be incremental. Major advances in IPM have been attained in specific regions with changes in philosophy, such as pest management through manipulating insect behavior. Are other major advances in pesticide reduction possible? In my opinion one way is with application of principles of community ecology to pest management. By manipulating the agroecosystem of the orchard we will be able to create orchards that are less dominated by pests and require less pesticides. This symposium was organized to present several examples of projects based on this philosophy of pest management and to provide a forum for discussion of how this type of ecological pest management can be implemented.

22-002

EVOLVING ECOSYSTEMS APPROACHES TO FRUIT INSECT PEST MANAGEMENT

S. B. Hill, Charles Vincent¹, Gérald Chouinard²
UWS, Richmond, University of New South Wales, Richmond, NSW, Australia,- 1 Horticultural Research and Development Center, Agriculture and Agri-Food Canada, 430 boul Gouin, Saint-Jean-sur-Richelieu, Québec J3B 3E6 Canada- 2 Service de recherches en phytotechnie, Ministère de l'Agriculture, des Pêcheries et de l'Alimentation du Québec, 3300 Sicotte, Saint-Hyacinthe, Québec J2S 7B8 Canada.

Ecological studies of agroecosystems have demonstrated both significant environmental problems associated with the intensive physical and chemical control of highly simplified crop production systems, and the largely untapped opportunities for knowledge intensive bioecological design and management of more complex systems. Barriers for change often overemphasise economics and lack of appropriate knowledge and technology. To address these barriers and to facilitate change, two approaches were proposed.

First, an overlapping three stage- efficiency, substitution, redesign (ESR)- evolutionary approach has been developed, together with a set of strategic questions for growers and support personnel.

Second, results of a decade of research on the behavior of the plum curculio, *Conotrachelus nenuphar* Herbst (Coleoptera: Curculionidae) are presented. Most adults emigrate from apple orchards in the fall and overwinter in surrounding forests.; they re-invade the orchards in spring. We implemented a program whereby only peripheral zones that have more than 1% oviposition scars are treated, resulting in a reduction of ca. 60% of insecticides normally recommended for this pest. Based on sound research and field information, apple growers experienced a shift in risk aversion to achieve a step forward in reducing insecticide use.

22-003

GLOBAL AND REGIONAL PEST INSECTS AND THEIR ANTAGONISTS IN ORCHARDS: SPATIAL DYNAMICS.

S. Dorn, Institute of Plant Sciences, Applied Entomology, ETH, CH-8092 Zurich, Switzerland

The spatial dynamics of herbivores gains importance when slowly acting pest management tools are employed. The temporal pattern of the techniques to be used in an agroecosystem has received some attention, particularly with respect to the preservation of certain natural enemies (e.g. predatory mites) as well as with respect to resistance management programs. The spatial pattern of the techniques applied in neighbouring plots, however, deserves increased attention especially when slowly acting pest management techniques are involved. This will be exemplified with *Cydia pomonella*. The flight capacity of this moth, dependant on age, sex and mating status, as well as its reproductive behaviour under the influence of sublethal insecticide doses were investigated in the laboratory.

The spatial dynamics of natural enemies are directed by a number of different cues. Knowledge of these cues may contribute to a more efficient biological control of pest species in the future. We investigated the searching behaviour of parasitic antagonists of *Phyllonorycter* spp. The role of herbivore induced volatiles as well as of vibrational stimuli will be discussed.

22-004

ROLE OF HEDGEROWS AND GROUND COVER MANAGEMENT ON ARTHROPOD POPULATIONS IN PEAR ORCHARDS

R. Rieux¹, S. Simon², H. Defrance²¹ INRA, Station de Zoologie, Avignon, France² INRA, SRIV Gotheron, St-Marcel-lès-Valence, France

With the failure of conventional pest management against the pear psylla *Psylla pyri* (L.) (HOMOPTERA: Psyllidae), strategies have been developed in order to enhance beneficial arthropod numbers (among them *Anthocoris nemoralis* (F.) (HETEROPTERA: Anthocoridae)).

Modifying the pear orchard vegetal environment is one of the integrated pest management (IPM) strategy that increases the agrosystem vegetal diversity allowing thus a better balance between phytophagous arthropods and their natural enemies.

We studied the arthropod fauna sampled from the pear orchard and its surroundings: hedgerow tree species canopies and different ground covers.

Communities were characterized by multivariate analysis: vegetal specificity for arthropod complex, predator-prey associations, subcommunities organization related to phytophagous families.

Inter-relationships between pear tree and hedgerow tree species were studied by Spearman's rank correlations. For instance, both *Fraxinus excelsior* L. and *Hedera helix* L. display a diversified fauna correlated with the pear community, but without significant correlation between each other. Their role towards pear is different: *F. excelsior* hosts specific psylla and cecidomyies, providing food for pear beneficial arthropods while *H. helix* rather acts as a shelter species.

As a ground cover, we tested: 1) bare ground, 2) natural green cover and 3) sown green cover. The structure and numbers of arthropod populations sampled in pear trees were different in these 3 types of management.

These results outline interactions between hedgerow (or ground cover) and pear arthropod populations. Manipulating the vegetal environment by selected species seems a hopeful way for optimizing the pear orchard IPM.

22-006

CHANGES IN THE POPULATION COMPOSITION IN IPM APPLE ORCHARDS UNDER CONTINENTAL CLIMATIC CONDITIONS IN HUNGARY

G. Jenser¹, Klára Balázs¹, Cs. Erdélyi¹, A. Haltrich², F. Kozár¹, V. Markó², Vera Rácz¹, F. Samu¹¹ Plant Protection Institute of Hungarian Academy of Sciences,H-1525 Budapest Pf. 102, Hungary, - ² University of Horticultural and Food Industry, H-1502 Budapest Pf. 53, Hungary

Hungary, in the Carpathian Basin has a continental climate and accordingly the fauna are different in many details from the fauna of the West European countries. There are many similarities and many dissimilarities between the phytophagous and zoophagous species occurring in the orchards of Hungary and of West Europe. The biology of pests, their predators and parasitoids may be different, too.

In a comparative experiment the effect of the broad spectrum and selective insecticides was studied on the population composition of arthropod population under this climatic conditions.

Owing to regular use of selective insecticides also some so-called secondary or potential pests different from those of West Europe appeared: San Jose scale, pear tingid (*Stephanitis pyri*), *Peritelus familiaris* (a curculionid beetle). Some pests, e.g. San Jose scale, codling moth have two, sometimes two and a half generations in the Hungarian orchards. These circumstances without doubt modify the develop of IPM system.

22-005

INFLUENCE OF FLOWERING PLANTS AND SELECTIVE INSECTICIDES ON OCCURRENCE OF BENEFICIAL AND HARMFUL ARTHROPODS, DISEASES AND YIELD.

E. Niemczyk, R. Olszak.

Research Institute of Pomology and Floriculture, 96-100 Skierniewice, Poland.

The observations were conducted on seven plots of apple orchard for four years. On six "integrated" plots only selective or partially selective insecticides (diflubenzuron, teflubenzuron, fenoxycarb, pirimicarb, phosalone) and fenitrothion were used. Also predatory mite *Typhlodromus pyri* (Phytoseiidae) was introduced. On five of those plots four species of flowering plants (wild heliotrope, buckwheat, roquette, mustard) were maintained in order to attract natural enemies of the pests.

The check plot (no 7) was intensively treated with broad spectrum of insecticides. Low differences in population of beneficial arthropods and pest species were visible within particular "integrated" plots. On all-except one-integrated plots the phytophagous mites (*Panonychus ulmi* Koch., *Tetranychus urticae* Koch.) were kept on very low level by *T. pyri* occurring during all four years in high numbers. Contrary, on check plot, *T. pyri* appeared sporadically and phytophagous mites exceeded threshold level. Four groups of beneficial arthropods occurred on "integrated" plots and flowering plants: spiders, predatory bugs lady beetles, parasitic wasps, lacewings and hover flies. Only three pest groups (leaf rollers, bugs and aphids), occurred in relatively high numbers and had to be sprayed. Several others important pest species in Poland (codling moth, apple sawfly, leaf miners, apple blossom weevil) appeared in low numbers and were not controlled at all. The obtained results indicated that using limited number of selective pesticides one can obtain the yield and quality of the apples similar on only slightly lower than yield from check plot sprayed more often with non selective pesticides.

22-007

ECOSYSTEM APPROACHES TO MANAGING INSECT PESTS OF FRUIT

Organizers: M.W. Brown¹ and E. Niemczyk²¹ - USDA-ARS, Appalachian Fruit Res. Sta., Kearneysville, WV, USA² - Research Institute of Pomology and Floriculture, Skierniewice, POLAND

AREAWIDE CODLING MOTH MATING DISRUPTION AND EFFECTS ON BIOLOGICAL CONTROL

J.F. Brunner¹, S.C. Welter², A. Knight³¹ - Washington State University, Tree Fruit Research and Extension Center, Wenatchee, WA, USA ² - Division of Insect Biology, University of California, Berkeley, USA ³ - USDA-ARS Fruit Research Laboratory, Yakima, WA, USA

Codling moth is the key pest of pome fruit production in the western USA. Most insecticides are directed at control of this pest resulting in the disruption of natural controls for many other pests. The control of codling moth through the use of pheromones, mating disruption, became a reality in 1991 with the registration of Isomate-C (Pacific Biocontrol). The potential of mating disruption as a control for codling moth was demonstrated in small orchard plots, 2-5 hectares, using different pheromone dispensing systems between 1992 and 1995. The level of codling moth control in mating disrupted blocks was as good as blocks using conventional control methods when sufficient dispensers were applied per hectare and pest densities were low.

The detection of codling moth populations resistant to organophosphate insecticides, especially in California, and the potential to document possible reversion of resistance prompted the establishment of an areawide management project, Randall Island, in 1993. In 1994 the USDA-ARS funded a codling moth areawide management project which established five sites of 160-500 contiguous hectares in three western states. Reduced use of broad-spectrum insecticides at these sites has resulted in higher levels of natural enemies of pests, such as aphids and pear psylla, and provided an opportunity to evaluate the augmentative release of selected biological control agents. At one site, Oroville, mating disruption has been combined with release of sterile moths to suppress codling moth populations.

22-008

ECOLOGICAL IMPACT OF THREE PEST MANAGEMENT STRATEGIES IN NEW ZEALAND APPLE ORCHARDS

D.M. Suckling, J.T.S. Walker¹, C.H. Wearing²

HortResearch, Lincoln, New Zealand - Havelock North, New Zealand - ² Clyde, New Zealand

Three apple pest management regimes are being compared for their ecological impacts, and their ability to ensure the economic production of high quality apples. Species diversity, pest status and fruit quality are being evaluated under i) Conventional, (ii) Integrated, and (iii) Biological fruit production. The Conventional system follows current export orchard practices with broad-spectrum pesticides, while the Integrated system uses a wider range of control methods, including minimal applications, preferably of selective pesticides. The Biological system uses mating disruption for codling moth, "Thuricide" for leafrollers, copper/slaked lime for diseases, and matting or mulches for weed control.

Conventional production has few insects present during the season and little damage at harvest, but increasing insecticide resistance problems and changing markets put the sustainability of this system in doubt. In the Integrated system, excellent control of lepidoptera has been achieved using tebufenozide, with little impact on natural enemies. Further development of the system is needed, but the economics appear favourable for future export. In the biological system, the fungicide sprays impact adversely on some natural enemies. The economic sustainability of this system is dependent at present on the local market price, and for the future on innovative technology to overcome quarantine pests.

22-010

THE INTERNATIONAL AGRICULTURAL RESEARCH CENTRES AND THE DEVELOPMENT OF INSECT-RESISTANT CROPS

M. Iwanaga

International Plant Genetic Resources Institute (IPGRI), Rome, Italy

The International Agricultural Research Centres (IARCs) of the Consultative Group on International Agricultural Research (CGIAR) are custodians of the world's largest *ex situ* germplasm collection. Collectively, they conserve about a half million accessions of major food and fodder crops. Active evaluation and use of the collections for host resistance breeding has been a major objective of the CGIAR Centres as a means to ensure sustainable crop productivity increases in an environmentally friendly way. Both collectively and individually, the Centres can provide many successful examples of the effective use of the collections for insect resistance breeding. This paper reviews and analyzes how effective alliances between entomologists, Centre specialists and collaborators in other disciplines can lead to insect-resistant crops. Challenges and opportunities for the further development of insect-resistant crops are examined in the light of concerted efforts on the part of key players in germplasm conservation and use.

22-009

GENETIC RESOURCE CONSERVATION AND PLANT RESISTANCE TO INSECTS

S.L. Clement, S.S. Quisenberry¹, S. Arnone², M. Cristofaro²

USDA, ARS, Regional Plant Introduction Station, Washington State University, Pullman, WA USA - 1 Department of Entomology, University of Nebraska, Lincoln, NE USA - 2 ENEA, Dipartimento Innovazione, Settore Biotecnologie e Agricoltura, Rome, Italy

There has been a steadily increasing output of printed material on the importance of plant biodiversity and genetic resource conservation to world agriculture. This literature, in the form of books and reviews, research articles, newsletters, and journals on genetic resources issues, has stressed the crucial role of genetic resources in the development of new, higher yielding, disease resistant, and better quality crops. As well, the usefulness of conserved germplasm (especially rice) for the development of insect resistant cultivars has been recognized. In this symposium, leading entomologists, plant scientists and policy makers affiliated with the International Plant Genetic Resources Institute (IPGRI), World Bank, International Research Centers, universities, industry, and national programs detail the importance of genetic resources for the development of insect resistant rice, wheat, maize, sorghum, beans, and root and tuber crops. Other invited speakers review the biotechnological properties in conserved germplasm for insect resistant crops and the use of germplasm for basic research in insect-plant interactions.

22-011

GERMPLASM EVALUATION FOR INSECT RESISTANCE IN RICE

E. A. Heinrichs, S. S. Quisenberry

Department of Entomology, University of Nebraska, Lincoln, NE, USA

Insects are major biotic constraints limiting the production of rice. Insect resistant cultivars have been bred for use as a major tactic in the development of IPM strategies and they have been shown to be compatible with biological, cultural and chemical control tactics. The world collection of rice germplasm, consisting of more than 100,000 accessions, has been extensively evaluated to identify donor accessions to be used as insect resistant parents in breeding programs at international agricultural research centers in Asia, Latin America and Africa. Commercial high yielding cultivars (30) with multiple resistance to insects and diseases have been developed at the International Rice Research Institute in the Philippines and one variety alone has been grown on 17 million ha in Asia. More than 70% of the commercial rice varieties in Latin America are resistant to the major pest, *Tagosodes orizicolus*. Insect resistant cultivars have contributed to yield stability and the success of the green revolution in rice. Biotechnology holds promise as a means to develop insect resistant rice cultivars where conventional breeding has not been successful. Transgenic rice plants containing the Bt toxin gene are currently in the evaluation stage.

22-012

THE VALUE OF CONSERVED WHEAT GERMPLASM EVALUATED FOR ARTHROPOD RESISTANCE

C. M. Smith¹, S. S. Quisenberry¹, F. du Toit²

Department of Entomology, Kansas State University, Manhattan, KS USA -1 Department of Entomology, University of Nebraska, Lincoln, NE USA - 2 PANNAR, P. O. Box 17164, 9338 Bainsvlei, South Africa

Resistance to 10 major arthropod pests of wheat has been identified in evaluations of over 40,000 *Triticum* accessions from several national and international germplasm collections in different countries of the world. Many of the sources of the resistance originated in varieties from southwestern Asia and southeastern Europe.

In the United States alone, the planting of arthropod resistant wheat cultivars currently saves over \$500 million worth of crop production costs and crop losses each year. On a global basis, the value of arthropod resistance in cereal crops is likely to be several billion dollars.

Different wheat varieties have been identified with resistance to the Hessian fly, *Mayetiola destructor* (Say); several aphids, including the greenbug, *Schizaphis graminum*, (Rondani); the Russian wheat aphid *Diuraphis noxia*, (Mordvilko); the grain aphid, *Sitobion avenae* (F.), the bird cherry-oat aphid, *Rhopalosiphum padi* (L.), and the rose grain aphid, *Metopolophium dirhodum* (Walker); the cereal leaf beetle, *Oulema melanopus* (L.), wheat stem sawflies; *Cephus cinctus* Norton and *C. pygmeus* (L.); the sunn pest, *Eurygaster integriceps* Put.; and the wheat curl mite, *Eriophyes tulipae* Keifer.

Resistance breaking biotypes of the Hessian fly and the greenbug have developed in response to numerous different vertical cereal resistance genes. These insect counteradaptations demonstrate the need for continual joint efforts of entomologists and plant breeders to improve cereal varieties for arthropod resistance.

22-014

GENETIC DIVERSITY OF SORGHUM, *SORGHUM BICOLOR* (L) MOENCH, A SOURCE OF INSECT RESISTANT GERMPLASMG. L. Teetes, G. C. Peterson¹, K. F. Nwanzu²

Department of Entomology, Texas A&M University, College Station, Texas, U.S.A. 77843-2475 - 1 Texas A&M University Agricultural Research and Extension Center, Route 3, Box 219, Lubbock, Texas, U.S.A. 79401-9757 - 2 International Crops Research Institute for the Semi-Arid Tropics, Patancheru P.O., Andhra Pradesh, India 502 324

The early domestication of sorghum in northeastern Africa and subsequent movement to many regions of the world, especially semi-arid, tropical areas, resulted in the evolution of a genetically diverse crop species. This genetic diversity has been exploited in crop improvement programs to increase yield and yield stability by introgressing beneficial genes for many traits including adaptation, grain quality, and biotic and abiotic stress resistance. Major effort has been made to increase the intrinsic ability of sorghum for defense against insect pests through genetic resistance. The photosensitive character of sorghum requires conversion to short, early genotypes for use in temperate regions of the world.

Identifying sorghums resistant to insect pests has been a successful endeavor, and is the focus of research programs by universities, international research centers, and national agricultural research systems. Most of the over 28,000 accessions in the world sorghum collection have been screened for resistance to many sorghum insect pests. Of nearly 50 important insect or mite pest species worldwide that attack sorghum pre- and post-harvest, genetic resistance has been found for about 30% of them. Greatest success in identifying and utilizing resistance has been for greenbug, *Schizaphis graminum* Rondani, sorghum midge, *Stenodiplosis sorghicola* (Coquillett), shoot fly, *Atherigona soccata* (Rondani), and several species of stem borers, armyworms, other aphids, and panicle infesting bugs. Insect resistant sorghums are used as an integrated pest management tactic. Interest in genetically resistant sorghums by industry is increasing as environmental concerns about pesticides increase.

22-013

GERMPLASM EVALUATION FOR INSECT RESISTANCE IN MAIZE

J.E. Foster, R.L. Wilson, F.M. Davis, and D. Barry

Department of Entomology, University of Nebraska, Lincoln, NE, USA

Insects are major constraints to the production of maize. In much of the world, resistant inbreds or hybrids of maize are grown as the major component of an IPM strategy for maize pests. The world collection of germplasm consists of a large number of entries that have not been totally evaluated for insect resistance, yet it is known that many private companies incorporate resistance into their commercial lines. The private sector companies do not reveal the amount of insect resistance utilized for proprietary reasons. However, public evaluation of widely grown hybrids reveal that seventy to ninety percent of all hybrids grown in the corn belt of the USA have some resistance to one or more insect pests. Multiple insect resistance is being utilized worldwide, especially in many programs affiliated with the international centers in Latin and South America. One or more stem borers are a major problem wherever maize is grown. Biotechnology offers increased tools for the introduction of genetic diversity. Transgenic maize containing the Bt toxin genes are being field tested and commercial hybrids are being marketed in the USA.

22-015

BEAN GERMPLASM RESOURCES FOR INSECT RESISTANCE

C. Cardona, J. Kornegay
Centro Internacional de Agricultura Tropical, CIAT, Cali, Colombia

For a crop such as common bean, usually grown by small farmers who can not afford expensive chemicals, host plant resistance may provide an economic, lasting way of overcoming insect and mite attack. Significant progress has been made in the past 15 years in the identification of sources of resistance to leafhoppers, bruchids, pod weevils, Mexican bean beetle, bean stem maggots, pod borers, chrysomelids, and other insects, as well as mites.

This paper reviews advances made in the identification and incorporation of resistance to major pests of beans. It makes emphasis on the value of conserved genetic resources for the development of bean lines and cultivars with resistance or tolerance to insects and mites, provides information on mechanisms and inheritance of resistance and breeding strategies to transfer resistance. It also covers aspects dealing with possible use of molecular markers to facilitate breeding, the value of wild relatives and other species in the improvement of beans, and the future use of host plant resistance as the foundation of integrated pest management systems.

22-016

UTILIZATION OF SWEETPOTATO GENETIC RESOURCES TO DEVELOP INSECT RESISTANCE

W. Collins, E. Carey¹, I. Mok², P. Thompson³, D. P. Zhang⁴
 Department of Horticultural Science, North Carolina State University, Raleigh, NC, USA - 1 International Potato Center, Nairobi, Kenya - 2 International Potato Center, Bogor, Indonesia - 3 Department of Plant and Soil Sciences, Mississippi State University, State College, MS, USA - 4 International Potato Center, Lima, Peru

Sweetpotato weevil (*Cylas* spp.; *Euscepes* spp.) is the most destructive insect pest of sweetpotato (*Ipomoea batatas* (L.) Lam.) in the world, occurring from the humid tropics to temperate growing areas. A number of Lepidopteran (*Omphisa anastomosalis*, *Megasiles* spp., *Synanthedon* spp.) and Coleopteran (*Alcidodes* spp. and others) pests can cause severe damage in drier environments. In the US, the WDS complex (wireworm, *Diabrotica*, *Systema*) causes significant damage.

Genetic resources of sweetpotato are extensive; much of the world's germplasm has been collected and is maintained in national and international genebanks. The most significant use of available genetic resources for insect resistance has been for sweetpotato weevil (USA, China, Philippines, Indonesia, India, Taiwan, Nigeria, Peru, Cuba) and for the WDS complex (USA). To date stable, high levels of resistance to sweetpotato weevil have not been found nor have mechanisms of resistance been identified. At present breeding efforts are concentrated on detecting and utilizing low to moderate levels of resistance in a wide array of germplasm. Transgenic sweetpotatoes with genes from unrelated species have been produced and field tested. They may provide an alternative and more effective method for incorporating resistance. Efforts to increase resistance to the WDS complex have been more successful. Moderate levels of resistance were located in populations developed from germplasm accessions and have been incorporated into commercially acceptable material.

22-018

PLANT GENETIC RESOURCES FOR STUDIES IN INSECT-PLANT INTERACTIONS

S.D. Eigenbrode¹, S. L. Clement²

1 Department of Plant, Soil and Entomological Sciences, University of Idaho, Moscow, ID USA - 2 USDA, ARS Plant Introduction Station, Washington State University, Pullman, WA USA

Genetic variation in crops has inspired basic investigation of ecological and evolutionary processes ever since Darwin and Mendel. Studies of insect-plant interactions, which have proliferated during the last third of the 20th century, have benefited from the availability of conserved genetic variation in crop plants. Within-species variation in crop plant susceptibility to herbivores has led to a deeper understanding of plant defenses, including glandular and nonglandular trichomes, various secondary compounds and enzymes such as protease inhibitors. Although the primary entomological use of plant genetic resources has been screening for and developing economic resistance to pests, there is potential for more use of these collections for basic research. Study of the genetic basis of defense, including quantitative aspects, genetic correlations of defense and other traits, and the molecular mechanisms of expression is facilitated in genetically conserved crops for which a large number of traits have already been identified and genetically mapped. Conserved germplasm from wild crop relatives provides additional opportunities including study of ecogeographic variation in plant defense against insects. Continuing collection of wild germplasm for crop improvement should be conducted to maximize the value of these for basic research. Thus, ancillary to their primary mission of providing the genetic basis for crop improvement, the germplasm collections of the national and international agricultural centers can continue to contribute to basic research in insect-plant interactions.

THE POTATO: GENETIC RESOURCES AND INSECT RESISTANCE

K. L. Flanders, S. Arnone¹, and E. B. Radcliffe²
 Department of Entomology, Auburn University, Auburn, AL USA - 1 ENEA, Settore Biotecnologie e Agricoltura, CRE Casaccia, Rome, Italy - 2 Department of Entomology, University of Minnesota, St. Paul, MN USA

The cultivated potato, *Solanum tuberosum* subsp. *tuberosum* L. is one of approximately 230 potato species (*Solanaceae*, Section *Petota*). This paper discusses the present status of potato breeding for resistance to insects and what the potential is in future. Genes from ten exotic potato species have been incorporated into North American and European potato cultivars, primarily for stress tolerance or disease resistance. Enhanced breeding lines are now being developed specifically for insect resistance. NYL 235-4 incorporates genes from *S. berthaultii* for resistance to Colorado potato beetle, *Leptinotarsa decemlineata* (Say); and other insects. Other examples of germplasm enhancement for insect resistance are the use of *S. pinnatisectum*, *S. commersonii*, *S. tarijense*, *S. sparsipilum*, and *S. sucrense* for potato tuber moth, *Phthorimaea operculella* (Zeller), resistance; and *S. stoloniferum*, *S. spegazzinii*, *S. toralapanum*, *S. chacoense*, *S. polytrichon*, *S. phureja*, and *S. sanctae-rosae* for green peach aphid, *Myzus persicae* (Sulzer), resistance. There are some sources of insect resistance that have been difficult to access using conventional breeding methods, and others that have not yet been accessed. One new method is somatic hybridization, which has brought genes from *S. bulbocastanum* into breeding lines. *Solanum bulbocastanum* has resistance to at least four insects, as well as to root knot nematodes.

BIOTECHNOLOGICAL APPLICATIONS OF PLANT GENES IN THE PRODUCTION OF INSECT RESISTANT CROPS

A.M.R. Gatehouse

Department of Biological Sciences, University of Durham, Durham, U.K.

Crops resistant to insect attack offer an alternative strategy of pest control to indiscriminate pesticide usage which has many undesirable effects, including those on the environment and humans. Transgenic plant technology can be a useful tool in producing resistant crops, by introducing novel resistance genes into a plant species.

Several different classes of plant proteins have been shown to be insecticidal towards a range of economically important insect pests from different orders; in some cases a role in the defence of specific plant species against phytophagous insects has been demonstrated. Genes encoding insecticidal proteins have been isolated from various plant species and transferred to crops by plant genetic engineering. Amongst these genes are those that encode protease and α -amylase inhibitors, lectins, and enzymes such as chitinases and lipoxigenases.

Examples of genetically engineered crops expressing insecticidal plant proteins from different plant species, with enhanced resistance to one or more insect pests from the orders Lepidoptera, Homoptera and Coleoptera are presented. The possibility of 'pyramiding' different resistance genes to improve the effectiveness of protection and durability is discussed and exemplified. The viability of this approach to crop protection is considered.

22-020

INSECT RESISTANT CROPS - THE FUTURE

S. S. Quisenberry, S. L. Clement¹, S. Arnone², M. Cristofaro²

Department of Entomology, University of Nebraska, Lincoln, NE USA - ¹ USDA, ARS, Regional Plant Introduction Station, Washington State University, Pullman, WA USA - ² ENEA, Dipartimento Innovazione, Settore Biotecnologie e Agricoltura, Rome, Italy

The conservation and use of genetic resources for the development of sustainable agricultural systems are an internationally recognized priority. Genetic variation for resistance to insect species has been shown in plants, both in natural and managed (agricultural) systems. Thus, genetic resources serve as a source of insect resistant germplasm that are necessary for the development and deployment of resistant cultivars in cropping systems. These resources have been effectively used to develop insect resistant cultivars in rice, wheat, maize, sorghum, beans, and root and tuber crops. Because the emphasis in agricultural systems has been in the selection of one or more genetically resistant traits that are recognized, environmentally stable, compatible with agricultural production systems, and provide an economic level of crop protection, resistance relationships in natural and managed systems must be understood. This will ensure sound approaches to germplasm conservation and subsequent deployment of insect resistant germplasm, and prevent or minimize the development of resistance-breaking insect pest biotypes. The use of biotechnological techniques coupled with an understanding of insect-plant interactions will also provide additional opportunities for conservation genetic resources that can be used to develop insect resistant cultivars in agricultural systems.

22-022

ERADICATION OF THE BOLL WEEVIL IN THE UNITED STATES THROUGH AN AREA-WIDE APPROACH

J. R. Coppedge

United States Department of Agriculture, Agricultural Research Service, Southern Crops Research Laboratory, College Station, Texas USA

The ongoing boll weevil eradication program was initiated in North Carolina, South Carolina, and Virginia in 1977; and in Arizona, California, and contiguous cotton producing areas of Northwest Mexico in 1985. The regional boll weevil eradication programs are cooperative federal-state-cotton producer efforts with a large percentage of the funding coming from the cotton producers within the region. The control measures used in these programs include pheromone trapping to delimit populations, judicious use of chemical treatments and cultural measures such as early stalk destruction and uniform planting. The key elements of these programs are early season treatments of malathion to limit the number of overwintered boll weevils which can colonize cotton, and multiple late season applications of malathion to reduce the number of boll weevils available to enter overwintering. Since program inception, the boll weevil has been eradicated in Arizona, Southern California, and Northwest Mexico, as well as in Virginia, North Carolina, and South Carolina. Eradication is almost completed in Florida, Georgia, and Southern Alabama. In some states (Virginia and North Carolina), the eradication of the boll weevil has resulted in up to a ten-fold increase in cotton acreage, and a 40 to 80 percent reduction in pesticide use. The program currently covers Northern Alabama, Northeast Mississippi, Middle Tennessee, and two areas in Texas. Texas has experienced some secondary pest outbreaks concurrent with the eradication program that are of serious concern to program officials and producers.

22-021

AREA-WIDE PEST MANAGEMENT: CONCEPTUAL, THEORETICAL AND HISTORICAL FRAMEWORK.

W. KLASSEN, TROPICAL RESEARCH AND EDUCATION CENTER, UNIVERSITY OF FLORIDA, HOMESTEAD, FL 33031, U.S.A.

Area-wide pest management is an important strategy for combating the entire population of insect pests within an ecosystem. It is commonly observed that the failure to suppress a mobile pest population in a small fraction of an ecosystem can result in very high economic damage throughout the ecosystem. For example in the case of the desert locust, whose geographical distribution extends from North Africa eastward to the Indian subcontinent, and whose widely separated breeding areas are linked by the seasonal migrations of the pest, the total population must be attacked in an organized manner in order to protect crops. Further the principle has emerged that fairly uniform suppressive pressure applied against the entire population of a pest species throughout the ecosystem results in a considerably greater reduction in its density than is achieved by a higher level of suppression of most but not quite all of the population.

Cases of area-wide pest management that have been of considerable historical importance in entomology include the suppression of the grape phylloxera, *Phylloxera vitifoliae* in Europe through the use of phylloxera-resistant root stocks beginning in 1872, the suppression of the cottony cushion scale, *Icerya purchasi* in California in 1889 by the vedalia beetle, *Rodolia cardinalis*, and suppression of the New World screwworm, *Cochliomyia hominivorax* in the southern USA and northern Mexico from 1962 to about 1975.

In cases where the presence of a pest species is highly damaging to public health or to an industry and where ecological isolation off the production area can be assured, the eradication of the pest population may be desirable economically and ecologically. Examples include the eradication of *Aedes aegypti* from a number of sites early in this century, the eradication of the cattle fever ticks, *Boophilus* spp. from USA during 1906-1943, and the first program to eradicate malaria by suppressing its anopheline vectors that was initiated in Venezuela in 1945.

22-023

AN ASSESSMENT OF THE CODLING MOTH SIT ERADICATION PROGRAM IN BRITISH COLUMBIA, CANADA

K. A. Bloem¹ and S. Bloem²

¹Okanagan-Kootenay SIR Program, Osoyoos, BC, Canada; ²USDA-ARS Yakima, Washington, USA

The codling moth, *Cydia pomonella*, is considered the key pest of apples and pears in the fruit growing regions of south-central British Columbia. This region includes about 7,500 Ha of commercial apple and pear production, as well as several urban centers with abundant backyard fruit trees and ornamental crabapple trees. In 1992, after 30 years of research and planning, an eradication program using Sterile Insect Release technology was implemented against this pest. Construction of the mass-rearing facility was completed in 1993 and sterile moths were released into area orchards for the first time in the spring of 1994.

The primary problem facing the Program has been a high wild population, resulting in inadequate overflooding ratios. Contributing to this problem has been poor dispersal activity of mass-reared moths relative to wild moths in cool spring weather. However, a number of operational changes in rearing and handling, coupled with an increased public information campaign and an increased effort from growers brought encouraging results in 1995. Most growers reported low codling moth damage (<0.5%) throughout the season and these reports were verified by field samples at harvest time.

The Program is currently operating only in the southern half of the treatment area. Eradication in some orchards is anticipated by the end of the 1997 growing season, and in all orchards of the south Okanagan by 1999. Clean-up efforts in the north Okanagan are scheduled to begin in 1997, with releases starting in the year 2000. It is hoped that by 2005 the entire area will be codling moth free.

22-024

DEVELOPMENTS IN THE AREAWIDE SUPPRESSION OF CODLING MOTH

C. O. Calkins

U.S. Dept. of Agriculture, Agricultural Research Service
Yakima, Washington, U.S.A.

A regional, multi-institutional program to assess, test and implement an integrated strategy for suppression of codling moth populations in fruit orchards was implemented. It was designed to alleviate the impact of neurotoxic pesticides on natural enemies while at the same time continue to control pest populations. This created the opportunity for use of more environmentally friendly control tactics for secondary pests. Five pilot test sites were located, one each in California and Oregon and three in Washington State, to demonstrate the utility of using mating disruption, biocontrol and, in one case, release of sterile moths to control codling moth and secondary pests with a minimum of neurotoxic chemicals. First year results indicated that this strategy could effect control of both codling moth and secondary pests with a greatly reduced amount of pesticides. The pilot programs will continue for four more years. Funding for this program is shared currently by the Agricultural Research Service and the fruit industry. Additional support is provided by State Universities in the three states. A series of research projects impacting the pilot test programs were funded as well. Eventually, this program will be adopted and supported entirely by the growers themselves.

22-026

RECENT DEVELOPMENTS IN CORN ROOTWORM AREA-WIDE MANAGEMENT STRATEGIES IN THE UNITED STATES

L.D. Chandler

U.S. Department of Agriculture, Agricultural Research Service, Northern Grain Insects Research Laboratory, Brookings, SD USA

Corn rootworms, primarily the western corn rootworm, *Diabrotica virgifera virgifera* LeConte, and the northern corn rootworm, *Diabrotica barberi* Smith and Lawrence, are among the most economically and environmentally important insects pests of United States maize production systems. Crop losses and control costs attributed to both species approach \$1 billion annually. Soil insecticides targeted at corn rootworm continue to represent the single largest use of insecticide in the United States. Scientists with USDA-ARS and the agricultural experiment stations of several midwestern states developed an alternative management strategy based on suppression of rootworm adults using a semiochemical insecticide-bait. The bait, composed of cucurbitacin, carbaryl, and insecticide carriers, is used to kill beetles before they lay the majority of their eggs and thus prevent economic infestations from occurring if maize is planted in the same field in the successive year. Commercially available baits use 95 to 98% less toxin active ingredient than traditional insecticide management programs.

Semiochemical insecticide-baits have been used successfully to manage corn rootworms at several sites in the United States corn belt. Management of beetles is most effective when done over a relatively large area. Using semiochemical insecticide-baits with other corn rootworm management tactics (crop rotation, biological control, etc.), state-of-the-art population monitoring technology, and new maize management technology will assist implementation of areawide management technology on portions of the estimated 2.5 million ha of maize production with significant corn rootworm populations. Expanded demonstration of this technology in the United States corn belt was initiated during the 1996 growing season and is expected to increase in scope during the next 3-5 years.

22-025

FRUIT FLY (DIPTERA: TEPHRITIDAE) AREA-WIDE INTEGRATED MANAGEMENT PROGRAMMES IN PROGRESS IN THE WORLD

J. Hendrichs, G. Ortiz

Insect and Pest Control Section, Joint FAO/IAEA Division of Nuclear Techniques in Food and Agriculture, Vienna, Austria

Tephritid fruit flies are major pests of fruits and vegetables. Because of the high economic value of the crops they attack and the significant damage a few gravid females can cause, the economic threshold for fruit fly damage is very low. In addition, fruit fly capacity for dispersal and survival in marginal and urban areas frustrates individual control efforts at the orchard level. Furthermore, quarantine restrictions impede trade in fresh fruit because of closed export markets or expensive post-harvest facilities needed to disinfest cargoes for shipment.

To overcome the unsustainable and often ineffective fruit fly control resulting from uncoordinated actions by individual producers, growers have been forced to coordinate their control efforts, including in non-commercial areas. Also, because of the quarantine restrictions, whole fruit producing regions have tended towards coordinating fruit fly control for certification of low prevalence or fly-free status.

As a result of the above, fruit fly area-wide management is becoming widely accepted as a necessity by the fruit industry. Area-wide campaigns, coordinated by grower associations or regional/national authorities in a number of countries, integrate various control methods, but often still rely on aerial protein-bait sprays or male-annihilation.

The Sterile Insect Technique (SIT), because of its specificity, environment-friendliness and compatibility with biological control of other fruit pests, is becoming the preferred area-wide management tool for fruit flies. Important successes have been achieved, most recently in Chile and Japan, where all pest fruit flies have been eradicated. Presently, there are area-wide fruit fly SIT control or eradication programmes in progress in Argentina, Australia, Costa Rica, Greece, Guatemala, Mexico, Pakistan, Peru, Philippines, Portugal, Thailand, and the USA, and under consideration or planning in some Mideastern, Maghreb and Central American countries, as well as in South Africa, Sicily, and Uruguay.

22-027

RECENT DEVELOPMENTS IN AN AREA-WIDE, INTEGRATED APPROACH FOR THE MANAGEMENT OF THE COTTON BOLLWORM, *HELICOVERPA ZEA* (LEPIDOPTERA: NOCTUIDAE)

J. E. Carpenter

Insect Biology and Population Management Research Laboratory, United States Department of Agriculture, Agricultural Research Service, Tifton, GA, USA

In the development of an area-wide, integrated approach for the management of the cotton bollworm, *Helicoverpa zea* (Boddie), individual control components are assessed for their potential for preventing or reducing the seasonal increase of bollworm populations. Candidate components include resistant plant varieties, natural enemies, biologicals, and autocidal control. Cultural practices and regulatory mandates also may be important area-wide management strategies.

Recent laboratory and field studies have revealed that many control components are compatible and, when used together, are often synergistic. Also, population models project that program resources divided among several control components may yield greater population suppression than program resources directed at a single control strategy. Current research efforts attempt to identify compatible control strategies, to develop efficient production and application technologies, and to integrate effective control strategies in an area-wide pest management program.

22-028

AREA-WIDE MANAGEMENT OF TOBACCO BUDWORM AND COTTON BOLLWORM WITH AERIALLY -- APPLIED INSECT VIRUSES IN THE UNITED STATES

D. D. Hardee and M. R. Bell

USDA, ARS, Southern Insect Management Laboratory, Stoneville, MS 38776 U.S.A.

Six years of research have shown that aerial application of a baculovirus (NPV) to early season hosts of the tobacco budworm, *Heliothis virescens* (F.), and the cotton bollworm, *Helioverpa zea* (Boddie), resulted in a significant reduction in the numbers of adults that emerge from treated areas and migrate to nearby cotton fields. We estimate that a properly timed treatment with good coverage of host plants with NPV consistently resulted in at least 70% of the insects on these plants dying from the virus as larvae or pupae. Long-range movement into and out of the treated areas is suggested as the cause of our inability to show a significant reduction in the numbers of eggs/larvae on cotton in the treated area compared to the surrounding area. Transfer of this technology to cotton producers in the Mississippi Delta area of the United States may result in future expansions of this program.

22-029

PINK BOLLWORM AREAWIDE MANAGEMENT

T. J. Henneberry

USDA-ARS, Western Cotton Research Laboratory
4135 E. Broadway Rd., Phoenix, AZ

Integrated pest management (IPM) and community-wide participation programs have been important factors in pink bollworm (PBW), *Pectinophora gossypiella* (Saunders) population suppression. Cotton IPM had its beginning with scouting programs that reduced numbers of acre treatments and costs per acre. In the San Joaquin Valley, CA, an areawide program has been conducted since 1968 to prevent establishment of migrating PBW. The program involves pheromone trapping, release of radiation-sterilized moths, cotton plant destruction and plowdown, and mating inhibition. Other large-scale areawide management systems with all available technology for PBW population suppression are in various developmental stages. However, in all PBW-infested cotton areas in Arizona and California, cotton scouting is practiced, and pheromone trapping and boll sampling determine the need for control based on established economic thresholds. Several aspects of PBW biology and ecology contribute to natural population regulation. In early season PBW suicidal emergence, natural enemies and high soil temperatures result in low (0.5 to 1.5 X) population increase. Resistant transgenic cotton (Bollgard™), short season cottons and pheromone-behavioral control are being implemented in varying degrees. In late-season, reducing development of the diapause PBW generation by eliminating host material or destroying diapause larvae using tillage or irrigation techniques are powerful and economical population suppression methods. Stalk shredding, burial of plant debris, disking, plowing and winter irrigation are vital management tools. Incorporating short-season methodology, resistant varieties and good cultural practices on an areawide basis can effectively reduce PBW populations to noneconomic levels.

22-030

THE CASSAVA MEALYBUG *PHENACOCCLUS MANIHOTI* (HOMOPTERA, PSEUDOCOCCIDAE) BIOLOGICAL CONTROL PROGRAM: A MODEL

Hans R. Herren

International Centre of Insect Physiology and Ecology, Nairobi, Kenya

The cassava mealybug (CM) *Phenacoccus manihoti* Matile-Ferrero has been introduced accidentally into Africa in the mid seventies. Its rapid spread and devastating damages threatened the major staple of over 200 million people. The CM arrived on planting material that had been introduced illegally, ignoring quarantine regulations banning introduction of vegetative plant material. With the potential to cause famine, the CM introduction caught the attention of governments and the international donor and research communities. In 1979, the International Institute of Tropical Agriculture (IITA) started work in biological control. This led to the creation of the IITA Biological Control Program (BCP) which developed a comprehensive research and training program and collaboration with scientists in Africa, Europe, and the Americas.

The strategy developed for the CM control covered systematic exploration of the likely areas of origin of the pest from southern California to Paraguay; rearing of the most promising natural enemies and detailed taxonomic, biological, and ecological studies in the area of origin and of introduction; their release in Africa over an infested zone one and a half times the area of the United States of America; an analysis of the cropping system and economic impact of the pest and its indigenous and introduced natural enemies and a large scale training and implementation program. The CM biological control program was a very rapid success because of the early discovery of the very efficient parasitoid *Epidinocarsis lopezi* (De Santis) (Hymenoptera, Encyrtidae). Its establishment, rapid spread and impact on the CM, which gave new confidence in biological control to policymakers and donors.

The success of the CM biological control program is due to the unique collaborative arrangements, the introduction of new technologies biological control practitioner had shunned until now. The program has already served as a model for several biological control projects and has left a legacy of trained personnel and infrastructure.

22-031

MANAGEMENT STRATEGIES FOR THE CONTROL OF SILVERLEAF WHITEFLY, *BEMISIA ARGENTIFOLII* (HOMOPTERA: ALEYRODIDAE)N.C. Toscano, N. Prabhaker Castle, T.J. Henneberry¹, S.J. Castle¹Department of Entomology, University of California,
Riverside, CA USA - 1 USDA-ARS, Western Cotton
Research Laboratory, Phoenix, AZ USA

Control of the silverleaf whitefly in California is dependent upon year-round insecticide use. The overlapping of crops which host whiteflies throughout the annual cropping cycle encourages high whitefly densities. As a result of this and the use of insecticides, there is a potentially high selection pressure for resistance development in the silverleaf whitefly. Because insecticides played an important role in crop protection strategies against this pest, an insecticide resistance management program was instituted.

A resistance monitoring technique using yellow sticky cards sprayed with grower available insecticides provided baseline data for a number of insecticides used for control of *Bemisia argentifolii* in California. Continuous monitoring of the whitefly populations for changes in resistance frequencies in large regions allowed decisions regarding effective management strategies to be formed. Whitefly insecticide resistance monitoring data and management strategies were communicated to farmers and pest control advisors via newsletters, newspapers, and Internet.

22-032

INTEGRATION OF THE STERILE INSECT TECHNIQUE (SIT) INTO SUB-REGIONAL TSETSE AND TRYPA NOSOMOSIS MANAGEMENT CAMPAIGNS

U. Feldmann, E. Opiyo¹ and J. Hendrichs

Insect and Pest Control Section, Joint FAO/IAEA Division of Nuclear Techniques in Food and Agriculture; - 1 Entomology Unit, FAO/IAEA Agriculture and Biotechnology Laboratory; International Atomic Energy Agency, Vienna, Austria

As the tsetse and trypanosomosis problem is characterized by many interdependencies, any intervention will have a wide range of immediate and longer-term implications. All environmentally acceptable tsetse/trypanosomosis intervention methods have their specific limitations and only a combination of several methods in an integrated, phased approach can effectively advance the establishment of viable agricultural systems. Since the problem affects entire sub-regions, area-wide integrated campaigns should be designed that are largely based on the participation of beneficiaries. This needs comprehensive planning that retains flexibility and a variety of intervention options, including eventual tsetse eradication.

The SIT is the environmentally safest intervention method and can be used even for inaccessible areas (aerial releases). Contrary to other tsetse control methods, the SIT has a unique efficiency pattern: increasing efficiency with decreasing target pest population density. A phased and complementary use of other methods, such as insecticide impregnated targets or the use of pour-on formulations of insecticides on domestic animals, followed by the SIT will have maximum efficiency throughout the intervention campaign. This approach is currently being demonstrated in a campaign to eradicate *Glossina austeni* from Zanzibar. FAO/IAEA has launched an initiative to upgrade the SIT to an economically attractive alternative for integration into area-wide sub-regional intervention campaigns. This involves R&D for the release of at least 500,000 sterile males per week over areas as large as 10,000 to 20,000 km² at a time.

22-034

PRELIMINARY FIELD PREDATION STUDIES OF THE OLIVE MOTH, *PRAYS OLEAE* (BERNARD)(LEPIDOPTERA: YPONOMEUTIDAE) IN GRANADA, SPAIN: A SEROLOGICAL APPROACH.

T.L. Morris¹, M. Campos¹, W.O.C. Symondson^{2,3}, J.E. Liddell³, N.A.C. Kidd², M. Jervis²

1 Estacion Experimental del Zaidin (C.S.I.C.), Granada, Spain- 2 School of Pure & Applied Biology, University of Wales, Cardiff, UK- 3 School of Molecular & Medical Biosciences, University of Wales, Cardiff, UK.

The olive moth, *Prays oleae* (Bernard) is one of the principal olive pests. A polyclonal antiserum was raised to aid the study of its associated natural enemy complex. The antiserum was absorbed against the olive bark beetle *Phloeotribus scarabaeoides* (Bernard), to eliminate nonspecific cross reactions. A detection limit was established taking into account background absorbance and the mean 2.5 times the standard deviation of the highest cross reacting species - to guard against false positives. Pheromone trapping and personal observations suggest that the detected predation was probably the olive moth rather than the cross reacting species. This agrees with the observed concordant phenologies of both predator and prey. The results are based on samples from two olive groves in Granada, one abandoned and the other managed, during the months of March through to September in both 1994 and 1995. In total some 20,000 are currently being tested representing over 100 species. Parasitoids and nonpredatory groups were excluded.

22-033

RELATIONSHIPS BETWEEN PHEROMONE TRAP CATCHES OF MALE OLIVE MOTHS, *PRAYS OLEAE* BERN. (LEPIDOPTERA: HYPONOMEUTIDAE), AND FLOWER AND FRUIT INFESTATION BY SUBSEQUENT LARVAL GENERATION

A.A. Bento, L.M. Torres¹, R.S. Sismeiro², J.I. Lopes²

Escola Superior Agrária de Bragança, Bragança, Portugal - 1 Universidade de Trás-os-Montes e Alto Douro, Vila Real, Portugal - 2 Direcção Regional de Agricultura de Trás-os-Montes, Mirandela, Portugal.

A three year study (1993-1995) on the relationship between catches of male olive moths, *Prays oleae* Bern., in sexual traps and flower and fruit infestation by subsequent larval generation, was carried out in one olive grove of the Cobrançosa cultivar, at Terra Quente Transmontana (North-eastern Portugal). The degree of *P. oleae* infestation, considered as the percentage of flowers and fruits with hatched eggs, was measured each year in 25 samples collected from each of 25 marked trees, within the experimental plot. Male moths were caught using five Delta pheromone traps, each year.

There was a significant linear relationship between larval infestation and accumulated adult catches. A regression model of the form: $Y = -0.0624 + 0.0002 X$, where X = accumulated adult catches and Y = percent of flower infestation, explained 83.6% of the variance for flower infestation, while a model of the form $Y = 0.0581 + 0.0003 X$ where X = as above and Y = percent of fruit infestation, explained 93.7% of the variance for fruit infestation. These results emphasize the role of sexual traps as a prediction and forecasting method for olive infestation by *P. oleae*.

22-035

OBSERVATIONS ON THE RESISTANCE OF SOME OLIVE CULTIVARS TO *PRAYS OLEAE*.

A. Lentini, G. Delrio

Istituto di Entomologia agraria, Università di Sassari, Italy

During 1995, in an olive grove in southern Sardinia the resistance of 21 cultivars to the carpophagous generation of *Prays oleae* Bern. (olive kernel borer) was studied. The number of eggs laid per olive varied from 0.02 to 0.74, and was higher in table varieties and in trees with lower production. Multiple regression analysis permitted to establish a greater relative contribution of the number of fruits per tree to the estimation of the infestation level. Predators and climatic factors determined an average mortality of 60% of the eggs. The fall of the drupes in the post-setting stage caused an ulterior reduction in the infestation and the percentage of olives with penetrating larvae resulted as 0.4-29%. The autumn drupe fall caused by the kernel borer was 0.1% - 20%, according to the variety. The reduction index, calculated from the ratio between the percentage of infested olives at the end of June and that of the infested fallen olives in autumn, was found to be negatively affected by the average weight of the drupes at harvesting, with values generally greater than 10 for oil varieties. The high resistance found in some cultivars with small drupes (oil producing varieties) is due to both the high fall in the post-setting stage that occurs with greater frequency for infested olives, and to intrinsic factors not yet identified that probably cause larval mortality.

22-036

INFLUENCE OF VARIETY AND MATURATION OF *OLEA EUROPAEA* L. FRUIT, ON *BACTROCERA (DACUS) OLEAE* (GMEL.) (DIPTERA: TEPHRITIDAE) ALCOHOL DEHYDROGENASE ALLELE FREQUENCIES.

M. Konstantopoulou, A. Manoukas and P. Hatzopoulos¹.

Institute of Biology "Demokritos" National Research Center, Aghia Paraskevi, Attiki, Greece - ¹ Laboratory of Molecular Biology, Agricultural University of Athens, Iera Odos 75, Athens, Greece.

The influence of the variety and the maturation of the host, olive fruit tree, *Olea europaea* L., on the olive fruit fly *Bactrocera (Dacus) oleae* (Gmel.) (Diptera: Tephritidae) was estimated, concerning alcohol dehydrogenase (ADH) allele frequencies.

Wild flies were collected as larvae from infested olives of different varieties from unsprayed olive orchards of Attiki, Greece. The varieties were: Koroneiki (small and large fruit size at an early and late stage of maturity), Megaritikiki, Kalamon and Oleaster. Allele frequencies were based on gel electrophoresis results. In order to evaluate the extent of influence in allele frequencies, chi-squares tests were performed between the different selected populations of olive fruit fly.

The ADH allele frequencies were not affected by the variety of the olive fruit and the stage of its maturity, in spite of the differences observed in the chemical composition of the varieties examined.

22-038

AN INTEGRATED PEST MANAGEMENT APPROACH FOR THE CONTROL OF THE OLIVE PESTS *BACTROCERA OLEAE* AND *PRAYS OLEAE*

B.E. Mazomenos, A. Mazomenou-Pantazi, D. Stefanou
Institute of Biology, NCSR "DEMOKRITOS"
P.O. BOX 60228, Aghia Paraskevi 15310, Greece

An integrated pest management (IPM) system to control the major olive pests, the olive fruit fly *B. oleae* and the olive moth *P. oleae* was tested in medium size olive orchards. Microbial pesticides, mating disruption and lure and kill methods, were successfully integrated. The results obtained revealed, that one Bt-treatment during the first year of (IPM) application to reduce the larval population in the flower generation of *P. oleae* and continuous application of the mating disruption for three years progressively reduced moth population from one year to the next. Fruit infestation remained at commercially acceptable levels. The lure and kill method is efficient and provides acceptable level of fruit damage in low fruit fly densities, while in high population densities additional control measures are required to keep the infestation within acceptable levels. Despite the fact, that the lure and kill method provides inadequate protection to the olive fruits, in years of high population densities of the fly, it is recommended to the farmers, since the method significantly reduced the number of toxic pesticides applications.

22-037

LOSS ASSESSMENT DUE TO *PRAYS OLEAE* BERN. AND *BACTROCERA OLEAE* GMELIN IN MOURA'S REGION (PORTUGAL). PRELIMINAR RESULTS.

I. Patanita, A. Mexia¹

Sub-sector Biologia e Protecção de Plantas, Escola Superior Agrária de Beja, Beja, Portugal, - ¹ Secção Autónoma de Protecção Integrada, Instituto Superior de Agronomia, Lisboa, Portugal.

A study was carried out in 1993, in an olive grove near Moura, to evaluate the losses caused by *Prays oleae* Bern. infestation in the flower and fruit generations and *Bactrocera oleae* Gmelin infestation on the preharvest fruit dropping.

For the *P. oleae* purpose, the number of flowers damaged by larvae was evaluated on marked branches of 25 trees from the Cordovil cultivar. In this year, however, the damage was very low. The fruit dropping from the whole of the tree canopies under observation was recorded weekly from fruit setting to harvesting. The percentage of olives which dropped as a result of *P. oleae* infestation was very high, 62.5% of the dropped fruits. The weight loss due to the olive moth was, on average in the 25 trees, 44.99% of the weight of harvest fruits (mean per tree equal to 10.98 kg).

For the *B. oleae* the damage of the fruits was assessed on 25 trees from the Cordovil cultivar, every two weeks. From each tree a sample of 25 dropped fruits was taken in each assess set.

The yield loss, which was calculated by weighing the fruit drop caused by *B. oleae* from the 25 trees, was on average, 15.3% of the fruit harvested from the canopy.

OLIVE GROVE ENTOMOFAUNA ANALYSIS AND FRUIT FLY CONTROL STRATEGIES IMPACT.

R. Petacchi, A. Minnocci.

Scuola Superiore di Studi Universitari e di Perfezionamento "S. Anna", Pisa, Italy.

Distribution, abundance and seasonal fluctuation of the entomofauna of a coastal olive grove not subject to herbicide treatments and therefore particularly complex from a biocenose point of view were analyzed over a two-year period. In addition, a comparison was made of the quantitative and qualitative effects on the insect community obtained by different insecticide treatments methods ("curative" and "preventive"), strategies ("calendar-based", "targeted") and active ingredient (Dimethoate and Delthamethrin) utilized in "preventive" control against *Bactrocera oleae* (Gmel.).

No substantial differences in qualitative presence of the insects were observed between the two years of sampling. *Diptera Brachicera* (except *B. oleae*), *Rhynchota Homoptera* (mainly *Cicadellidae*) and *Microhymenoptera* were the groups presents constantly, the first two at a very high percentage. At a quantitative level, on the other hand, a marked difference between the total numbers of insects captured was found, in agreement with the infestation level (number of fruit flies) collected. These alternations were a consequence of the different climatic state and olive production level. In spite of these differences the structure of the insect community and the seasonal fluctuation of the groups remained substantially stable.

Treatments appeared to have a quantitative negative impact on the olive-grove entomofauna. This occurred immediately after the period of the treatment but also during the period of rapid population growth. This finding did not differ substantially between the two olive fruit fly control methods ("adulticide" and "larvicide") or between the two different active ingredient or treatment strategies used in the preventive method. However, a more prolonged effect on insect presence was observed in the larvicide trial. Data thereby obtained could be used as biological indicators of the health of the agroecosystem.

22-040

SIDE EFFECT OF THE AIR BAIT TREATMENT AGAINST THE OLIVE FLY AND THE APPLICATION OF ALTERNATIVE METHODS FOR THE OLIVE FLY CONTROL IN CRETE

A Kalaitzaki¹ & S. Michelakis²

1. Mediterranean Agronomic Institute of Chania, Alsyllion Agrokipio, 73100

2. Agricultural Research Centre of Chania, Agrokipio, 73100

The olive fruit fly (*Bactrocera oleae* Gmel.) is the most important insect pest in the olive groves of Greece and specially of Crete. The air bait sprays as well as the improper applications of the ground bait sprays, carried out until today, for the insect control, have caused side effects on the beneficial insects as well as consequences on the whole environment. For the improvement of an integrated control system, the development of the mass trapping system was tested during 1989 - 1993 in different regions of Chania prefecture. The first two years the plywood insecticide treated traps baited with sex attractant and ammonium bicarbonate were tested in olive groves of about 120.000 and 435.000 trees respectively. The comparison between the trap zone and the control (conventional olive groves) was made on the basis of the adult olive flies captures in McPhail traps, on the olive fruit infestation by the olive fly as well as on the beneficial insect population. The olive fly captures were significantly higher in the control compared to the trap zone and the total average number of olive flies was 22,9 and 14,3 respectively. The final olive fly infestation in the olive fruits was little higher in the trap zone than in control. During 1992 the same kind of trap, baited with the same lures but with different arrangement of trap and density of sex pheromone, were tested in olive groves of about 120.000 olive trees. During 1993, 3 different kinds of traps (plywood trap, insecticide paper trap and cloth trap) were tested in olive groves of about 96.000 trees. During these last two years the olive fly captures were significantly higher (almost double) in the control compared with the trap zone and the final olive fly infestation in the olive fruits was the same in the control and the trap zone. The beneficial insect population at the trap zone was higher compared with the air and the ground bait spray zones.

22-042

LURE AND KILL-TARGET DEVICES USED IN SPAIN TO CONTROL OLIVE FLY (B. OLEAE GMEL.).

A. MONTIEL. Ingeniero Agrónomo. Jefe del Servicio de Agricultura y Ganadería. Delegación Provincial de la Consejería de Agricultura y Pesca. Junta de Andalucía. Avda. de Madrid, 25. 23008 JAEN (Spain).

In an attempt to have a lure and kill system which was sufficient long in duration, target devices were developed which consisted of olfactory food and sex attractants which lure the insects onto a Killing device composed of cotton cloth treated with an insecticide.

The long-life sex pheromone lure coupled with the ammonium salt lure for females were used as the attractant sources in such targets used at a rate of one per tree. The insecticide used was a pirethroid formulated for good Knock-down and persistence.

Another target device system was tested which consisted of a yellow piece of cloth treated with an insecticide at the start of the field season. One target device was suspended in each olive tree and treated periodically with either food and/or sex pheromone attractants in a sprayable formulation. The food-lure is applied to the cloths when the flies are not sexually active while a microencapsulated sex pheromone and food mixture is applied when the flies are shown to be sexually active from monitoring traps.

22-041

Development of a simulation model for olive fly population management

A. Cossu¹, P.C. Cresto², G. Delrio³, L. Locci¹, M. Mannoni²

1.SAR Servizio Agrometeorologico Regionale della Sardegna (Sassari)

2.CNR - Istituto di Ricerca sul Controllo Biologico dell'Ambiente (Sassari)

3 Istituto di Entomologia agraria - Università di Sassari, Italy

A computer simulation model of olive fruit fly (*Bactrocera oleae*) populations was developed for use in IPM programmes. The model is of discrete, deterministic, box-car type, using hourly air temperature as the main driving variable, drupe availability and infestation percentages of first olive fly generation as input variables. The individual development for the summer generation is simulated by an empirical sub-model, function of temperature and fruit maturation rate; for the following generations the sub-model is based on temperature data.

The population abundance is estimated by means of a fecundity sub-model, temperature and age dependent, and by a mortality sub-model based on meteorological data and on published life-tables.

The variability in development and fecundity is generated applying the Montecarlo stochastic method.

The results obtained from simulation were compared with field data on population abundance collected over a ten years period in Sardinia (Italy).

The model is able to accurately predict the phenology, whereas the population abundance is sufficiently simulated for only half of the observed years.

22-043

AUSTRALIAN CITRUS INTEGRATED PEST MANAGEMENT

G.A.C. Beattie and D. Smith¹

NSW Agriculture, Biological and Chemical Research Institute, Rydalmere, NSW, Australia - ¹Queensland Department of Primary Industries, Maroochy Horticultural Research Station, Nambour, Qld, Australia

Since 1970, effective integrated pest management (IPM) programs have been progressively implemented for the main foliar and/or fruit pests of Australian citrus - scales, mealybugs, and mites, and citrus leafminer (*Phyllocnistis citrella* Stainton). The successes of these programs have led to dramatic reductions in the use of broad-spectrum pesticides. A significant proportion of orchards are not sprayed annually for the control of pests.

Research by State departments of agriculture, universities, and the Commonwealth Scientific and Industrial Research Organisation (CSIRO) laid the foundations for the successes. However, most recent developments have been based on close cooperation between the State departments and private consultants operating as scouts and/or commercial insectaries.

Citrus growers now fund research and development through a levy, and these funds are matched 1:1 by the Australian Government through its Horticultural Research and Development Corporation (HRDC). Voluntary contributions from private companies are also matched by HRDC, and the government's Australian Centre for International Agricultural Research supports cooperative research with developing countries.

Technology transfer is achieved through publications, field days, workshops, and farm visits with government researchers and advisors, and private consultants playing key roles. Technology transfer through regional groups of growers ('Citigroups') is also supported by HRDC, and HRDC funded personnel contribute to industry newsletters. A technology transfer plan is a prerequisite for HRDC funded research. HRDC recently supported publication of a major book 'Australian Citrus IPM' and Australasian Biological Control Inc. also recently published 'The Good Bug Book' with government assistance. Despite the successes, ongoing research and technology transfer is required to address the threat of new pests, the spread of existing pests such as citrus leafminer, and changing practices and climate. Most of the industry is also poorly equipped to properly use IPM compatible chemicals such as petroleum spray oils (PSOs) which play a crucial role in IPM when natural enemies fail or are absent. This critical situation is being addressed.

22-044

BRAZILIAN INTEGRATED INSECT AND MITE PEST MANAGEMENT OVERVIEWS. Gravena¹

1-IPM Consultant in Instituto Agrônomo de Campinas, Centro de Citricultura "Sylvio Moreira", Cordeirópolis, State of S. Paulo, Brazil. There are three main varieties explored in the Brazilian citriculture, being 2 for processing purposes (Valencia e Natal) and 1 for also fresh market (Pera). The actual 800.000 hectares of citrus produced ca. 1,280 million tons of fruits. From this amount about 30% was for local consume. The IPM is nowadays being applied in ca. 25% of the citrus area and is separated in two fruit destinies: for industry and for fresh market. The principal tactics is the key pest monitoring that is rather complicated because of the citrus leprosis mite, *Brevipalpus phoenicis* Geijskes, which is associated to a virus disease. This mite caused about 10% of loss last year and can repeat the present year again due to the long dry weather period that favors the mite. About 50 million US\$ was spent in 1995/96 by the citrus growers to control this mite. The IPM depends hardly on the pest monitoring workers that always need to be trained in pest scouting for IPM decision make. We can estimate that there are already more than 1.000 scouters in the citrus area of State of São Paulo and can increase to 2.500 following the rest of the IMP implementation. Among other pests, the xylem feeders Cicadellinae, vectors of the xylem living bacteria *Xylella fastidiosa*, and the armored scale insect, *Selenaspidus articulatus* Morgan are also important for the IPM practice in Brazil. The IPM implementation is being done by the state govern agriculture division, by citriculture growers associations and by some private companies in training, consulting and research activities. The other tactics that are being developed by the growers and researchers are: the environment pest manipulation, the natural biological control knowledgement, and the pest control by nutrition (fertilizer). Artificial and classical biological control are still undeveloped in Brazil but are already included in the government institutional programs.

22-046

AN OVERVIEW OF INTEGRATED PEST MANAGEMENT ON CITRUS IN SOUTHERN AFRICA

V. Hattingh

Outspan Citrus Centre, PO Box 28, Nelspruit 1200, South Africa

Most of the potentially damaging insect pests on citrus in southern Africa have associated complexes of natural enemies capable of effectively regulating pest population levels. These complexes consist of indigenous species and the products of classical biological control projects in combination with the fortuitous introduction of natural enemies through unknown means. There is therefore ample potential for implementation of integrated pest management practices. However, several other factors make profitable and sustainable production of citrus in southern Africa particularly challenging. Heavy reliance on exports to highly sophisticated and distant markets, requires high economic returns to ensure profitability and quality standards are therefore exacting. Furthermore, growers have to deal with a very wide range of highly damaging pests. The existence of particularly problematic pests such as the indigenous thrips *Scirtothrips aurantii* hinders further development of IPM. Likewise, the availability of insect growth regulators for the control of red scale *Aonidiella aurantii*, which has become resistant to organo-phosphates in most of the region, has also detrimentally affected IPM implementation. This has been directly through the impact on biocontrol agents and indirectly through the consequent changes in control strategies adopted for other pests. Requirements of export markets regarding residues and production practices, resistance and the development of augmentative mass releases of natural enemies, are expected to extensively influence IPM in the region in the future.

22-045

INTEGRATED PEST MANAGEMENT IN MEXICAN CITRUS
E. Ruíz Cancino

Facultad de Agronomía, Universidad Autónoma de Tamaulipas. Cd. Victoria, Tam. México.

México is one of the major citrus-producers countries in the world, with an almost four million ton annual production from 360,000 ha (30% of fruit production). Valencia orange, mexican lime, Marsh grapefruit and Dancy mandarin are the major crops. Four management levels are present in orchards from 11 states.

Citrus rust mite, Texas citrus mite, false spider mite, Mexican fruit fly, citrus leafminer, citrus whitefly and citrus snow scale are the major pests. Besides, 67 insect and mite species are recorded as secondary, occasional or potential pests.

Natural enemies of 30 species are present in different production areas, mainly Aphelinidae, Eulophidae, and Coccinellidae.

A national IPM Program is in progress with fruit flies, in coordination with USDA to control the main four species, including Mexican fruit fly. Although citrus rust mite and other mite species are usually the key pests, no IPM program is working yet.

Citrus leafminer arrived México in 1994. One IPM program is developing now against this important pest. The status of several parasitoids on scales and other Homoptera is under revision, because exploded populations of several pest species are occurring in different states.

22-047

A BIOLOGICALLY BASED IPM PROGRAM FOR CITRUS IN CALIFORNIA'S SAN JOAQUIN VALLEY

R. F. Luck, L. D Forster, J. G. Morse

Department of Entomology, University of California, Riverside, CA

San Joaquin Valley is the major citrus producing region in California. Its proportion of the state's production is increasing as southern California's production is displaced by urbanization. Unlike southern California growers who rely on biologically based IPM, growers in the San Joaquin Valley apply four or five broad-spectrum pesticides annually to suppress their pests. Pesticide resistance in two key pests, reduced pesticide availability, production economics, and public pressure to reduce pesticide use are forcing growers to adopt new pest management practices. These changes involve the development of a biologically-based IPM program. The program is based on augmentative releases of commercially produced *Aphytis melinus* to suppress armored scales, conservation of resident natural enemies to suppress lepidopteran pests and citrus red mite, and a combination of selective pesticides and resident natural enemies to suppress citrus thrips and the other pests. Current research focuses on documenting the efficacy of the *Aphytis* releases and determining the economics of pest control. A complex of natural enemies are responsible for armored scale suppression and the IPM program has cut total pest control costs in half while maintaining or improving fruit quality and production levels.

22-048

INTEGRATED PEST MANAGEMENT FOR CITRUS IN FLORIDA, USA
J.E.Pena, J.L.Knapp¹, H.W.Browning¹

Tropical Research and Education Center, University of
Florida, Homestead, Florida 33031, USA-1 Citrus Research and
Education Center, Lake Alfred, Florida USA

In the past 40 to 50 years, the complex 857,000 acre citrus
industry of Florida has evolved into a highly complex mono-
cultural system grown in four major areas of the state. The
regions differ in cultivars grown, in climate and pest
problems. Numerous phytophagous mites, armored and unarmo-
red scales, mealybugs, whiteflies, aphids, weevils, leaf-
miners and some opportunistic insects represent the arthro-
pod fauna common to Florida citrus. Classical biological
control and augmentation of natural enemies within a
defined IPM strategy has been used in some areas of citrus
production today. Basic biology, pest seasonality, sampling
tactics and monitoring has been studied for citrus rust
mite *P. oleivora*, broad mite *P. latus*, citrus red mite, *P.*
citri. Biological control of mites with predators and fungi
has been researched but further research is needed to impro-
ve their persistence and performance in the field.
Success in biological control of armored scales (Florida
red scale, purple scale) has changed their status from
important to minor pests. Generally, citrus snow scale, *U.*
citri, is considered the only armored scale not adequately
controlled by beneficial insects. The unarmored scales,
mealybugs and whiteflies have been the focus of intensive
classical biological control efforts. Lately, integrated
pest management work is focused in citrus root weevils
(*Pachneus* sp., *D. abbreviatus*), citrus leafminer *P.*
citrella and brown citrus aphid (*Toxoptera citricida*).

22-049

THE USE OF *CRYPTOLAEMUS MONTROUZIERI* (MULSANT)
FOR THE CONTROL OF *PLANOCOCCUS CITRI* (RISSO) IN
CRETE-GREECE.

H. A. Hamid (1) and S. Michelakis (2)
1. Mediterranean Agronomic Institute of Chania,
Alsyllion Agrokipio, 73 100 - 2. Agricultural
Research Center of Crete, Chania, Agrokipio
73 100

The citrus mealybug *Planococcus citri* (Risso)
(Coccoidea: Pseudococcidae) is a major pest of
citrus orchards in Crete. In order to reduce
the use of chemical insecticides, experiments
were carried out in Crete, to introduce integra-
ted control methods of the pest. On potted
orange trees, infested with the citrus mealybug
Planococcus citri (Risso), in a greenhouse the
predator *Cryptolaemus montrouzieri* Mulsant was
released in three predator: prey ratios (1:10,
1:15 and 1:30). The effect of *Cryptolaemus mon-*
trouzieri on populations of the citrus mealybug
was also compared with *Nephus reunioni* Furs and
a chemical (methidathion) under controlled
temperature (25-30 C) and relative humidity (55-
70%), where mealybugs were maintained on pumpkins
(*Cucurbita moschata* (Duch)). Five adult beetles of
each predator were released. Methidathion was
applied at a concentration of 0.1%.

The predator *Cryptolaemus montrouzieri* effe-
ctively reduced mealybug populations. The pre-
dator:prey ratio 1:15, in most cases, resulted
in lower mealybug populations. When compared
with *Nephus reunioni*, *Cryptolaemus montrouzieri*
caused a significant reduction in mealybug popu-
lations. In most cases, significant differences
were not detected between *Cryptolaemus montrou-*
zieri and methidathion, which indicates the
effectiveness of the predator *Cryptolaemus*
montrouzieri in the control of the citrus
mealybug populations.

22-050

APPROACHES ON BIOLOGICAL CONTROL OF *DIALEURODES CITRI* (ASHMEAD) IN TURKEY

N. Uygun, M. R. Ulusoy, İ. Karaca, U. Kersting
Dept. of Plant Protection, University of Çukurova,
01330 Adana, Turkey

Whiteflies are the most serious pests on citrus in Turkey. Up to now
we determined six species: *Dialeurodes citri* (Ashmead), *Parabemisia*
myricae (Kuwana), *Aleurothrixus floccococcus* (Maskell), *Paraleyrodes*
minei Iaccarino, *Bemisia tabaci* Gennadius and *B. afer* Prisner et
Hosney. Two species, *A. floccococcus* and *P. minei* were determined in
Turkey for the first time near the Syrian border in the east
Mediterranean region in August 1994. To date, both species are
restricted to this small area and no further spread was observed. *B.*
tabaci and *B. afer* were only occasionally observed on citrus and
became never a serious problem. *P. myricae* invaded Turkey in 1982,
but was successfully controlled by the introduced parasitoid
Eretmocerus debachi Rose et Rosen within only three years. Since
then, only very few *P. myricae* are found on citrus in Turkey, which
are, however, mostly parasitized.

Presently the most serious pest in Turkey is the citrus whitefly, *D.*
citri, which is attacked by ten indigenous or introduced predators and
two parasitoids, respectively. The predator *Serangium parcesetosum*
Sicard and the parasitoid *Encarsia lahorensis* Howard have been
mass reared and released since 1990 and both species established well
in citrus orchards. *E. lahorensis* was not very effective in controlling
high population densities of *D. citri*. In contrast, *S. parcesetosum*
seems to be a very promising agent in controlling the citrus whitefly.

22-051

MONITORING OF *PLANOCOCCUS CITRI* (RISSO) POPULATIONS WITH PHEROMONE TRAPS

José Carlos Franco

Sec. Aut. Prot. Integrada, Instituto Superior de Agronomia,
Lisboa, Portugal

Monitoring refers to broad, often qualitative, sampling of pests or
their effects used to trigger more precise, quantitative sampling
programs. It includes surveys, trapping and possibly remote
sensing.

In order to test the "Scale trap" (Isagro-EniChem, Italy) system,
with dispensers baited with 0.25 mg of the synthetic sex
pheromone of the citrus mealybug (CM), *Planococcus citri*
(Risso), in the monitoring of its populations, a study was
conducted in the South of Portugal, during 1991-94. Trapped
males were counted weekly.

The period of male activity began between 10 and 31 of March and
ended between 26 of December and 13 of January. Only the first
two male flights were well defined, but just the second was
detected in all the four plots studied. The first male flight reached
its maximal between 23 of March and 27 of May and the second
between 9 of June and 12 of July. The data suggest that the
phenology of the CM in Faro and Tavira (Algarve) evolve 7 to 15
days earlier than in Setúbal.

The possibility of using "Scale trap" as a tool to initiate sampling
of fruits and to define the opportunity of intervention either in
biological control (e.g., releases of *Leptomastix dactylopii* How.)
or in chemical control of CM is discussed.

22-052

THE DAMAGE CAUSED BY *PLANOCOCCUS CITRI* (RISSE) ON CITRUS GROVES

E.B. Silva, A. Mexia

Secção Autónoma de Protecção Integrada, Instituto Superior de Agronomia, Tapada da Ajuda, 1399 Lisboa Codex, Portugal

The citrus mealybug, *Planococcus citri* (Risso), is usually considered a key pest of citrus groves in several countries, including Portugal, due the damage caused by this species.

There is a lack of understanding in which way the citrus production components are affected by the activity of the citrus mealybug, eventhought the already existing knowlegde about the different types of damage caused by this pest.

The results of several studies carried out in Portugal concerning the damage caused by the citrus mealybug on sweet orange groves, showed that only medium to high population densities caused a significant reduction of production, both in fruit weight and fruit size. However, the settlement of low densities of the citrus mealybug colonies affected fruit external appearance, caused commercial depreciation, due to fruit coloration, fruit splitting and presence of clorotic spots. On the other hand, in terms of commercial depreciation it seems that the number of fruits infested with citrus mealybug colonies is more important than the dimension of the colonie settled on the fruit. More than the importance of damage caused by the citrus mealybug on citrus groves, this fact can also affect the risk estimate and economic threshold for *P. citri*.

22-054

EVOLUTION OF THE POPULATION OF THE CITRUS LEAF MINER AND ITS PARASITIDS DURING 1995 IN VALENCIA (SPAIN)

J. Costa-Comelles, J.L. Aliaga, R. Vercher y F. García-Marí

Departamento Producción Vegetal. Universidad Politécnica Valencia, Spain.

The level of new flushes and the population density of the Citrus Leaf Miner (CLM) *Phyllocnistis citrella* Stainton and its parasitoids has been studied in a Navel orange orchard from Catadau, Valencia (Spain) during 1995. Out of 6 periods of new flushes, only 2 bear a high number of shoots per tree, in Spring (from February to April) and at the end of the Summer (August-September). CLM populations are very low or absent in Spring and reach high levels (3-4 mines per leaf) from June to October, so the main damage to the new vegetation of the trees is produced in August and September. The CLM developing stage was closely related with the lenght of the leaf, and not with date or length of the shoot. The percent parasitism by *Pnigalio* sp. increases steadily, being below 10% between May and July, from 10 to 20% in August and September, and above 30% in October. Host-feeding was also observed in this parasitoid. The number of adults of CLM captured in sticky traps of several colors was low and without differences. *Sympiesis gordius* (Walker) and *Sympiesis gregori* Boucek, parasitoids of apple leaf miners, were released in the orchard.

22-053

AUTOCTONOUS PARASITIDS OF THE CITRUS LEAF MINER IN VALENCIA (SPAIN)

R. Vercher, M.J. Verdú¹, J. Costa-Comelles y F. García-Marí

Departamento Producción Vegetal. Universidad Politécnica - Valencia, Spain.

Instituto Valenciano de Investigaciones Agrarias. Moncada (Valencia), Spain.

Thirty groves were sampled between September and November 1995 in the Citrus area around Valencia (Spain), by collecting and observing at the laboratory 100 Citrus Leaf Miner (CLM) late stages, and placing shoots in evolutionaries for parasitoid adults. All the orchards had parasitoids, and the rate of active parasitism was very variable, ranging from 10% to 60%, without much relationship with previous history of chemical sprays in the grove. Parasitism increases with time as Autumn progresses. The five species of parasitoids identified were, from more to less abundant, *Pnigalio* sp., *Cirrospilus pictus* Nees, *Cirrospilus vittatus* Walker, *Sympiesis gregori* Boucek and *Chrysocharis* sp. *Pnigalio* sp. is the overall predominant species in the groves in Summer, being gradually replaced in Autumn by both species of *Cirrospilus*. It parasitizes mostly L4, but also L3 and pupae, and its ratio male:female is near 2:1. Both species of *Cirrospilus* are parasitoids of L3 and their male:female ratio is 1:1. They can act incidentally as hiperparasitoids of *Pnigalio* sp.

22-055

ANALYSIS OF A REPRESENTATIVE EXPERIMENT OF BIOLOGICAL AND IPM ON CITRUS ORCHARDS IN EASTERN SICILY

V. Vacante¹, C. Pucci¹, A. Ragazzi²

1. Dipartimento di Protezione delle Pianta, Università della Tuscia, Viterbo (Italy).

2. AGRIPROGEST, Lentini (SR), (Italy)

The results of a research carried out within a big project of IPM applied all through the 1995 in the Sicilian Citrus cultivation with the U.E. funds (C.E.E. Reg. 2078/92, A1).

In this context, 172 variously cultivated firms were investigated (i.e. orange, clementine, tangerine) and placed in the Siracusa, Catania and Messina provinces. The total examined surface is 498.48 ha wide, with a firm dimension varying between 0.13 and 21.90 ha. The biggest entomological problems are represented by aphids (*Aphis gossypii* Glover, *Toxoptera aurantii* B.d.F. and *Aphis spiraeicola* Patch), Citrus Leaf Miner (*Phyllocnistis citrella* Stainton), Mediterranean Fruit Fly (*Ceratitis capitata* Wied.) and Citrus Mealybug (*Planococcus citri* Risso) infestations; the pathological problems are represented by *Phytophthora* sp.

With regard to the new strategy the 12.20 % of the firms has employed beneficials organisms (*Leptomastix dactylopii* Howard and *Cryptolaemus montrouzieri* (Mulsant)) and mineral oils, generally sprayed in the wintertime, the 10.46 % only mineral oils, the 27.90% has utilized only pesticides (but not minerals oils), the 34.29 % has employed during the year mineral oils and pesticides and the 15.11 % of the firms has not treated. The authors discussed these results on the technical, economical, ecological and toxicological outlines.

22-056

CONTROL MEASURES OF *LOPHOLEUCASPIS JAPONICA* COCKERELL (HOMOPTERA:COCCINEA) THROUGH INTEGRATED CITRUS PESTS MANAGEMENTE.S.Tabatadze, V.A.Yasnosh¹

Department of Biological Control, Kanchaveli Plant Protection Research Institute, Tbilisi, Republic of Georgia, - 1 Same

Japanese scale, *Lopholeucaspis japonica* Ckll. is one of the main pest on citrus plants in the Black Sea coast of Georgia. At present the indigenous natural enemies are great value in controlling this pest. Natural enemies complex includes mainly the aphelinid parasitoids, predatory coccinellids, mites, spiders and also new pathogenic fungus *Aschersonia* sp., unknown earlier in the Caucasus.

The economical threshold of scale is 20 - 25 scales/cm² of trunk or brunches. The criteria of the natural enemies efficiency is 50% of scale population destroying by parasitoides or predators. These indices were used in order to provide the rational control measures. If it is necessary the sprays by mineral oil (1% in summer and 2% in other periods) or by 0,5 % - 1% applaud against the first and second instar larvae are recommended.

22-058

SUCCESSFUL CONTROL OF THE MEDITERRANEAN FRUIT FLY *CERATITIS CAPITATA* (WIED.) (DIPTERA: TEPHRITIDAE) BY MASS TRAPPING METHOD, IN AN ORANGE ORCHARD IN GREECE.

Zervas G.A.

Biology Institute, National Center for Scientific Research "Demokritos", Athens 153 10, Greece.

The application of the mass trapping method for two consecutive years, protected successfully from medflies an orange orchard of 600 trees. Two types of Lure and Kill traps were applied. A trap of the reversed cup type baited with Trimedlure which killed male flies and a modified plastic McPhail trap baited with food attractant (hydrolysed protein) which killed female flies. Medflies attracted in both traps were killed by an insecticide layer put inside the traps. Traps installed in both years at the beginning of September at a density of one trap every second tree for the males and one trap every third tree for the females, decreased in the monitoring traps the natural population of males from 34 to 0.5 and 38 to 0.5 flies/trap and females from 38 to 2 and 72 to 0.9 flies/trap the first and the second year respectively, within 20 days after installation. The low catches in the monitoring traps remained till the end of December. The attractants in the two types of traps were only once replaced during the period of application (after 40 days), while the killing factor was not renewed.

Samples of fruit collected from the orchard, exhibited very low infestation (one pupa was found in 150 fruits and a few oviposition stings) for the first year, while the second year no pupae or stings were found in the samples collected.

Since, no sprays with insecticides were applied in the orchard for two consecutive years, the release of the parasitoid *Cales noacki* (Hymenoptera) for control of the white fly *Aleurothrixus floccosus* Maskell (Homoptera) was made possible.

MANAGEMENT OF CITRUS PESTS IN EGYPT : FROM RESEARCH TO PRACTICE

A.H. Rasmy

National Research Centre, Dokki, Cairo, Egypt

A successful natural control of the citrus pests was achieved after 3 years of discontinuing pesticide applications in an orange orchard. The population of the citrus brown mite initially increased to damaging levels after discontinuing pesticides, then declined and was maintained at a very low level. This coincided with a gradual increase in the populations of the predacious mites. Regarding other citrus pests, the populations of the fruit fly and aphids were maintained also at low levels, but scale insects increased to a noticeable number at the third year. Thereafter, a pest management program based on maximising the role of natural enemies and minimal use of pesticides was applied to maintain the citrus key pests at low levels, but the question now is how can we mitigate damage caused by the citrus leafminer invaded Egypt citrus in 1994.

22-059

MEDITERRANEAN FRUIT FLY INTEGRATED CONTROL: COMBINATION OF GENETIC SEXING STERILIZED MALES WITH LURE AND KILL OF WILD FLIES

A.P. Economopoulos^{1,2}, B. Papadopoulos¹, N. Mantzos¹, P. Mavrikakis¹,P. Dimakis¹, H. Dretakis¹, M. Yassar¹, M. Dretakis¹ and M. Fafoukakis³¹ Institute of Molecular Biology and Biotechnology, Foundation for Research and Technology Hellas, Heraklion, Crete, Greece² Department of Biology, University of Crete, Heraklion, Crete, Greece³ Fodele Community, Greece

In a pilot field application on 5,000 citrus in the island of Crete, successive weekly releases of about one million gamma-sterilized medfly males were applied from June till December. The test area was protected against wild medfly immigration with lure and kill trap "barriers" of parapheromone and food attractant. Before releases, male parapheromone lure and kill was applied to minimize wild male numbers in the test area.

The above method produced substantial protection of fruits from medfly, as compared to controls and previous year. No insecticides were applied in the test area against the medfly.

22-060

COMPARISON OF *ANAGYRUS SAWADADII* ISHII AND *LEPTOMASTIX DACTYLOPII* HOWARD (HYMENOPTERA : ENCYRTIDAE) PARASITIZING IN THE CITRUS MEALYBUG, *PLANOCOCCUS CITRI* (RISSO) (HOMOPTERA : PSEUDOCOCCIDAE)

T. H. Su and C. K. Su

Department of Entomology, National Chung Hsing University, Taichung, Taiwan, Republic of China

Laboratory experiments were conducted to study the relationship between the citrus mealybug, *Planococcus citri* (Risso) and its two endoparasitoids, *Anagyrus sawadadii* Ishii and *Leptomastix dactylopii* Howard. In choice tests, *A. sawadadii* parasitized on the first and the second instar nymphs of *P. citri* and produced 4.6 and 14.3 progeny, with sex-ratio of 28.6% and 41.9%, respectively. *L. dactylopii* parasitized on the third instar nymphs and the adult of *P. citri* and emerged 4.3 and 8.5 progeny, with sex-ratio of 34.6% and 39.2%, respectively. In no-choice tests, *A. sawadadii* parasitized on the first instar nymphs and the second instar nymphs of *P. citri* and had 12.9 and 22.7, with sex-ratio of 16.9% and 33.1%, respectively. *L. dactylopii* parasitized on the third instar nymphs and the adult of *P. citri* and emerged 7.5 and 19.1 progeny, with sex-ratio of 28.9% and 38.5%, respectively. Developmental duration of *A. sawadadii* in the first instar nymphs of *P. citri* was 30.4 days. *L. dactylopii* parasitized the third instar nymphs of *P. citri* took 21.8 days to develop that was longer than that of the adult of 19.7 days. Adult longevity at 20°C, 25°C, 30°C and 35°C was 35.8, 20.6, 13.8 and 7.7 days for *A. sawadadii*, and 40.9, 24.9, 15.7 and 7.3 days for *L. dactylopii*, respectively. The impact of regulation was demonstrated through parasitoid exclusion experiment: *P. citri* cohorts exposed to these two species of parasitoids for 6 months, number of mealybug on pumpkin were 0.12/cm², whereas cohorts protected from parasitoid, number of mealybug on pumpkin were 0.78/cm².

22-062

DEVELOPMENT OF EGGPLANT VARIETAL RESISTANCE TO INSECTS AND DISEASES VIA PLANT BREEDING

G. L. Rotino, E. Perri, N. Acciarri¹, F. Sunseri², S. Arpaia²

Istituto Sperimentale per l'Orticultura, Section of Montanaso Lombardo (LO), Italy - 1 Istituto Sperimentale per l'Orticultura, Section of Monsampolo del Tronto (AP), Italy - 2 Metapontum Agrobios, Metaponto (MT), Italy

Eggplant (*Solanum melongena* L.) is an important Solanaceous crop mainly cultivated in the tropical, Asian and European regions. The major objectives of breeding are the development of high-quality, pests and diseases resistant varieties. In the countries where intensive and successive cropping is practised the main important goal is to develop varieties resistant to soil-born diseases (fungi, bacteria and nematodes), insects, mites and fruit rot.

Incorporation of resistance genes into eggplant cultivars has been, so far, very limited because of lacking of desirable traits into the eggplant gene pool or sexual incompatibility with resistant wild related species.

The present communication will review the source of resistance genes to pest and diseases available both in the eggplant gene pool and in the wild *Solanum* relatives. Taking into account the genetic determinism of the resistance traits, the possible strategies for eggplant resistance breeding will be discussed with emphasis on approaches based on integration of classical breeding methods (crosses and selection) with biotechnological ones (anther culture, somaclonal variation, genetic transformation and protoplast fusion).

Experimental evidence on breeding for resistance against some soil-born diseases and pests using such approaches will be presented.

22-061

THE CITRUS LEAF-MINER, *PHYLLOCNISTIS CITRELLA* STANTON, IN SICILY: DEVELOPMENT, DAMAGES AND STRATEGIES OF CONTROL

A. Nucifora, M.T. Nucifora

Istituto di Entomologia Agraria, Università di Catania, Catania, Italy

The authors relate on the sudden widespread of the infestation of *Phyllocnistis citrella* Stanton all over Sicily during summer 1995 and on its development during Autumn and Winter 1995-96.

The study goes on to review briefly the damages on the infestation and its economics relevance.

The authors then go on to discuss the negative results of attempts to control the infestation by use of different pesticides and to discuss the wider problem of integrated control of the infestation and the mechanical, physical techniques related to it. They believe the conclusions that in the case of yielding citrus crops the best solution can be found in the employment of biological control by the indigenous entomophagy and by the introduction of some exogenous entomophagus. In the Eastern coast of Sicily we have found *Pnigalio mediterraneus* Ferriere, *Cirrospilus pictus* Nees and *C. vittatus* Walker, where in the western one Liotta *et al.* (1966) have noticed the presence of nine autoctonus species: *Cirrospilus diallus* Walker, *C. pictus*, *Ratzeburgiola incompleta* Boucek, *Pnigalio* spp. (three species), *Apotetrastichus sericothorax* (Szelényi), *Apotetrastichus* sp., *Teleopterus exsias* (Walker), *Chrysocharis* sp., *Neochrysocharis* sp. The last three species were unnoted as parasitoids of *Ph. citrella*.

In the case of plants of the nurseries and also for ornamental citrus little plants the Authors suggest the use of mechanical control via the isolation in structures covered by screening nets.

Topgrafted plantings and young plantings should be protected by use of chemical control; but better by the use of sucks of screening net, in which each plant must be imprisoned. Biological control by predators can be applied inside them.

22-063

MUTAGENESIS OF *BACILLUS THURINGIENSIS* GENES TO ENHANCE EXPRESSION IN EGGPLANT

R. Iannacone, P.D. Grieco and S. Arpaia

Metapontum Agrobios, Metaponto, ITALY

Bacillus thuringiensis (Bt) genes have been widely used to confer insect resistance in transgenic plants. The expression level of wild type (wt) Bt genes in plants was indeed very low due to the presence, in the nucleotide sequence, of potential regulatory signals for eukaryotes and to an unfavorable codon usage in plants. In this work a modified version of the Bt gene Bt43, belonging to the CryIII class (Coleoptera-specific genes) and active against Colorado Potato Beetle (CPB), was used to confer resistance to this target pest in transgenic eggplant.

The Bt43 gene was modified using a Polymerase Chain Reaction approach. Most of the destabilizing sequences were replaced and the codon usage was adjusted to more closely resemble that found in plant genes.

The homology between the Bt43 the modified gene (BtM) was of 84%. The BtM gene was transferred in eggplant via *Agrobacterium tumefaciens*. The introduction of neutral translationally mutations in the Bt43 coding region resulted in a significant increase of its expression level at mRNA and protein level. Transgenic eggplants showing high resistance against CPB were obtained.

22-064

ENGINEERING TRANSGENIC EGGPLANT (*SOLANUM MELONGENA* L.) RESISTANT TO THE COLORADO POTATO BEETLE (CPB, *LEPTINOTARSA DECEMLINEATA* SAY)

G. Jelenkovic¹, S. Billings¹, Q. Chen², J. Lashomb³, G. Ghidui⁴

¹ Department of Plant Science, Rutgers University, New Brunswick NJ, USA-² Chinese Academy of Agricultural Sciences, Beijing, China-³ Department of Entomology, Rutgers University, New Brunswick, NJ, USA-⁴ Rutgers Research and Development Center, Bridgeton, NJ, USA

A chimeric construct, containing the synthetic *cryIIIA* (*Btt*) gene, the NPTII selectable marker and the *uidA* reporter gene, was incorporated via *Agrobacterium tumefaciens* into eggplant, variety Hibush. The synthetic *cryIIIA* gene, altered at the nucleotide level without changing the amino acids of the toxic protein by Dr. J. Kemp of New Mexico State University, Las Cruces, is adapted for high expression in plant cells. To verify the transgenic status, GUS assays were performed on over 300 plants, from which 185 were confirmed to be transgenic. Physical incorporation of the chimeric construct was further confirmed by Southern analysis of about 30 transgenic plants; both single and multiple site incorporation of the *Btt* gene were found. Resistance to CPB was assessed by: a) placing egg masses of CPB on leaves of plants grown in the growth chamber; b) placing first-instar larvae on detached leaves; c) observing 173 transgenic plants under field conditions. Approximately 60% of the transgenic plants displayed a very high level of resistance to CPB. No larvae survived on the resistant plants longer than 50-60 hours after hatching. Upon selfing, the transgenic plants with a single construct segregate in the S₁ generation in a mendelian fashion.

22-066

PREDICTING DURABILITY OF COLORADO POTATO BEETLE RESISTANT EGGPLANT GERMPLASM

S. Arpaia, K. Chiriatti, G. Giorio.

Metapontum Agrobios, Metaponto, ITALY

A simulation model was developed to predict the possibility of adaptation by *Leptinotarsa decemlineata* Say to CryIIIB toxin expressed in transgenic eggplant. Two different field deployment strategies were analyzed. In case of completely transgenic fields, a fast buildup of resistance to the toxin by the Colorado Potato Beetle is expected (frequency of resistance allele will overcome 0.5 in the second year of cultivation), even if the plants express moderate levels of toxins. A mixed planting of transgenic and non transgenic clones could, instead, allow to preserve a longlasting efficacy of the germplasm. The main features of the beetle's biology leading to these results in mixed fields are:

- a) fitness costs are associated to the adaptation of *Leptinotarsa decemlineata* to the CryIIIB toxin;
- b) migration of adult beetles from harvesting potato fields into eggplant fields constantly happens late in the growing season. This causes a sensitive reduction of the allele frequency in the beetle population.

22-065

RESISTANT MANAGEMENT PRACTICES FOR COLORADO POTATO BEETLE (COLEOPTERA: CHRYSOMELIDAE) IN VEGETABLE CROPS

G. P. Dively, J. J. Linduska

Department of Entomology, University of Maryland, College Park, MD USA

Transgenic potatoes containing δ -endotoxin expressing genes of *Bacillus thuringiensis*, and the systemic/contact insecticide, imidacloprid (Admire 240FS, Bayer Corp.), are highly effective against Colorado potato beetle (CPB), *Leptinotarsa decemlineata* (Say). Because of the season long constitutive expression of the protein toxin and the systemic action of imidacloprid, these "high dose" strategies exert strong selection pressure which may result in rapid pest adaptation. Several resistant management practices were developed to maximize the long-term utility of these novel products. Bioassay techniques and baseline levels of CPB susceptibility to the purified δ -endotoxin and imidacloprid were established as a reference for tracking resistance development. Seed mixtures, in which nontransgenic plants were randomly interspersed with transgenic plants within a field, were evaluated as a refuge strategy to maximize the probability that resistant CPB will mate with susceptible individuals and produce susceptible offspring. Two practical approaches for creating refuges with soil applications of imidacloprid were also tested: perimeter barriers and row mixtures. These spatial applications of treated and untreated plants in a field significantly reduced costs over whole-field treatments and provided a refuge so that some portion of the CPB population was not subjected to selection.

22-067

INTERPLANTING WITH SELECTED FLOWERS TO ENHANCE PARASITOID & PREDATOR ABUNDANCE.

J.M. Patt, J.H. Lashomb, G.C. Hamilton¹

Department of Entomology, Rutgers University, New Brunswick, NJ USA - ¹ Rutgers Cooperative Extension, New Brunswick, NJ USA

Interplanting with flowering herbaceous plants increases parasitoid and predator efficacy in agroecosystems. However, few details are available on the compatibility of these insect's foraging ability with floral architecture (=the spatial relationship of the nectary with other floral parts). Here we show that laboratory evaluations of parasitoid and predator foraging performance on flowers with disparate floral architectures can be used to select the flowers that will be most successful in promoting beneficial insect abundance and species diversity in agroecosystems. We focused on the egg parasitoid *Edovum puttleri* (Hymenoptera: Eulophidae) (EP) and major predators of the Colorado potato beetle, *Leptinotarsa decemlineata* (Say) (Coleoptera: Chrysomelidae), in commercial eggplant fields in New Jersey (USA).

Laboratory evaluations of flowers with disparate floral architectures demonstrated that EP can forage in flowers with exposed nectaries ("suitable" floral hosts) but cannot forage in flowers with partially-hidden nectaries ("unsuitable" floral hosts); while predators such as *Coleomegilla maculata* (Coleoptera:Coccinellidae) and *Chrysoperla carnea* (Neuroptera: Chrysopidae) can forage on flowers with both exposed and partially--hidden nectaries.

Preliminary studies in eggplant fields interplanted with selected flowers indicated that the presence of "suitable" flowers significantly increased predator abundance with a corresponding increase in CPB egg mass and larvae mortality.

22-068

BIOCONTROL OF ARTHROPOD PESTS IN EGGPLANT IN ITALY

S. Maini, G. Nicoli¹, M.G. Tommasini¹, M. Benuzzi², M. Mosti²
 Dipartimento di Biotecnologie Agrarie ed Ambientali, Università di Ancona,
 Italy - 1 Istituto di Entomologia 'G. Grandi', Università di Bologna, Italy - 2
 Biolab, Cesena, Italy

The arthropod pests of eggplant in Italy are approximately 10 species. In northern Italy, the Colorado potato beetle (CPB) *Leptinotarsa decemlineata* (Say) (Coleoptera Chrysomelidae) is the key pest. Before the registration of preparations based on *Bacillus thuringiensis* subsp. *tenebrionis* (B.t.t.), trials were carried out on biocontrol using seasonal inoculative releases of *Edovum puttleri* Grissell (Hymenoptera Eulophidae) (EP). For several years we reared this egg parasitoid on CPB. Releases of EP pupae gave satisfactory control of CPB infestation in eggplant grown under plastic tunnels. Mass production of EP was not developed due to high labour cost for the CPB and EP rearings. Another reason was also the success of CPB control by means of B.t.t. Five cases involving others arthropod pests and biocontrol agents are listed. (1) Spidermite, *Tetranychus urticae* Koch (Acarina Tetranychidae) is usually controlled by only one release of *Phytoseiulus persimilis* Ath.Hnr. (Acarina Phytoseiidae). (2) Whiteflies are more dangerous in southern Italy; their control can be achieved by releasing the predator *Macrolophus caliginosus* Wagn. (Rhynchota Miridae) that attacks both *Trialeurodes vaporariorum* (Westw.) and *Bemisia* spp. (Rhynchota Aleyrodidae). Releases of the two parasitoids *Encarsia formosa* Gah. and *Eretmocerus mundus* Merc. (Hymenoptera Aphelinidae) can improve the efficiency of the predator used alone. (3) *Frankliniella occidentalis* (Perg.) (Thysanoptera Thripidae) and other thrips species control is conducted releasing *Orius laevigatus* (Fieb.) (Rhynchota Anthocoridae) as soon as the first thrips captures in blue sticky traps are made. (4) *Aphis gossypii* Glover, *Myzus persicae* (Sultz.), *Macrosiphum euphorbiae* (Thom.) (Rhynchota Aphididae), in relation to location and rate of infestation can be controlled, respectively, by releases of *Aphidius colemani* Viereck and/or *Lysiphlebus testaceipes* Cres. (Hymenoptera Aphididae), *Chrysoperla carnea* (Steph.) (Neuroptera Chrysopidae), and/or *Harmonia axyridis* Pallas (Coleoptera Coccinellidae). (5) *Liriomyza* spp. (Diptera Agromyzidae) are well controlled by releases of *Diglyphus isaea* (Walker) (Hymenoptera Eulophidae). In some areas, the implementation of biocontrol in eggplant will be particularly difficult due to the necessity of releasing many species of natural enemies. However, farmers can choose this strategy since all the biocontrol agents herein listed are sold in Italy by biofactories.

22-069

DEVELOPMENT AND USAGE OF SEQUENTIAL SAMPLING IN A BIOLOGICAL CONTROL INTENSIVE PEST MANAGEMENT PROGRAM

G.C. Hamilton
 Rutgers Cooperative Extension, Department of Entomology,
 Rutgers University, New Brunswick, NJ USA

Sequential sampling has been used in agricultural systems to rapidly estimate pest densities relative to the need for instituting control measures for many years. In the mid to late 1980's a biological control intensive pest management (BCIPM) program targeting the Colorado potato beetle (CPB) was implemented in New Jersey for eggplant. This program included releases of the egg parasitoid, *Edovum puttleri* for the suppression of beetle populations; monitoring of fields; and recommendations for chemical sprays. Initially, CPB populations were monitored twice a week by determining the mean number of eggmasses, small larvae (1st and 2nd instars), large larvae (3rd and 4th instars) and adults found on 100 plants selected from within each field. Decisions were then made regarding parasitoid effectiveness and the need for insecticides. This type of time intensive monitoring program, however, limited the number of hectares that could be managed by the program. Due to this, two sequential sampling programs, one for eggmasses and a second for adult and larvae, were developed. The sampling program for adults and larvae utilizes a single economic threshold that accounts for differences in the consumption rates between life stages. The placement of larvae and adults on an equivalent basis accelerates monitoring by allowing the sampler to count individuals independent of life stage. Both sampling programs were field tested prior to release to the BCIPM program and have been used since 1992.

22-070

DEVELOPMENT AND IMPLEMENTATION OF A BIOLOGICAL CONTROL INTENSIVE PEST MANAGEMENT PROGRAM IN EGGPLANT

James Lashomb

Department of Entomology, Rutgers University,
 New Brunswick, New Jersey USA

The methods and techniques of implementing a biological control intensive pest management program in eggplant are discussed. The biology and behavior of *Edovum puttleri* a parasitoid of the Colorado potato beetle are presented as a major tool in preventing plant damage.

22-071

ERADICATION OF *CYDIA POMONELLA* (L.) FROM WESTERN AUSTRALIA

W. G. Thwaite, W. Woods¹

NSW Agriculture, Agricultural Research & Veterinary Centre, Orange,
 N.S.W. Australia - 1 Western Australia Department of Agriculture,
 Midland, W.A. Australia

Cydia pomonella (L.) is a worldwide pest of apples and pears. Japan and Western Australia are the only two major apple growing regions of the world free from the pest. In January 1993, *C. pomonella* was found at Bridgetown in the south-west of Western Australia and three months later further south at Albany. Following the first discovery, an eradication campaign was commenced based on a protocol developed through a consensus process during the early weeks of the campaign. The protocol, which needed only slight modification for the Albany eradication, had two aims: (1) local containment of the outbreaks and (2) surveillance of other fruit growing districts and urban areas to ensure the region was returned to its former codling moth free status, an important trade advantage.

The eradication campaign had four components: regulation, sanitation, pest monitoring and public education. Regulatory powers allowed the affected areas to be quarantined, restricted the movement of any fruit likely to be a host of the insect and allowed likely sources of infestation to be checked. Fruit, trees, and in some cases whole orchards, were removed and any material likely to harbour the pest burned and buried. A cover spray program was required on commercial orchards. Sex pheromone traps were used to monitor adults in the infested areas and a grid of traps was established elsewhere in the state to ensure the pest had not moved from the quarantined areas. The presence of larvae was monitored by examining trees, dissecting fruit and by trapping with trunk bands. An extensive public awareness campaign backed up the field operations.

By December 1995, *C. pomonella* had not been detected anywhere in Western Australia for two years and it was concluded that eradication was successful.

22-072

INTEGRATED PEST MANAGEMENT IN AUSTRALIAN APPLE ORCHARDS

W. G. Thwaite

NSW Agriculture, Agricultural Research & Veterinary Centre, Orange, N.S.W. Australia

The Australian apple industry has advanced towards integrated pest management (IPM) in response to consumer concern about use of pesticides on fruit crops and to the development of resistance in several pests. The need for an IPM program was foreseen in the mid 1960s when a national research project was undertaken which provided valuable information on the ecology of the apple pest complex throughout southern Australia. This was followed by integrated control of pest mites based on phytoseiid mites with the strategic use of acaricides and the avoidance of pesticides toxic to predators. Industry funding for research was formalised in 1988 and since then the Australian apple and pear industry has made a substantial financial commitment to IPM related research. Private industry, including agricultural chemical companies and producers of biological control agents, has also contributed to the IPM research and development effort.

The current focus is on the control of *Cydia pomonella* (L.), codling moth, the key pest in apple orchards in south-east mainland Australia, and the native leafroller *Epiphyas postvittana* (Walker) which is a problem in the cooler south. Conventional control relies on a program of the insecticide azinphos-methyl over 4-5 months of the growing season. One of the insect growth regulator compounds, fenoxycarb, was introduced as an IPM approach to lepidoptera control in 1991. One advantage of this approach has been reduction (after three seasons without azinphos-methyl) in the pest status of *Eriosoma lanigerum* (Hausmann). Other "soft" insecticide alternatives to azinphos-methyl are under trial. Recent research has evaluated mating disruption for both *C. pomonella* and *E. postvittana*. The value of supplementary sprays of azinphos-methyl or fenoxycarb with mating disruption of *C. pomonella* has been examined. Codling moth granulosus virus and an insect parasitic nematode have been investigated as biological control alternatives for *C. pomonella* compatible with IPM.

22-074

THE PEST ARTHROPOD MANAGEMENT IN ORCHARDS AT HILLY RESERVOIR AND OTHER DISTRICT NEAR WATER RESOURCES

C. P. Shen

Department of Scientific Research Management, Laiyang Agricultural College, SHANDONG, CHINA

During 1992-1993, the main pest arthropods and management for them in orchard where were near reservoir, river and sea, at Laiyang, Gaomi and Penglai, Shandong, China had been studied. It was defined that: 1 The arthropod community structure at different times in apple orchard. The leading pest species were *Aphis spiraeocla*, *Tetranychus viennensis*, *Panonychus ulmi*, *Carpocapsa nipponensis*, *Spilonota lechriaspis*, *Myzus malisuctus* and *Heliothis armigera*. 2 The spatial distribution of *Spilonota lechriaspis* larvae and the influence of releasing *Trichogramma*. The spatial distribution of overwintering and first generation *S. lechriaspis* larvae, pupas and so on were negative binomial distribution. 3 The control effect of Clofentezine to *Tetranychus viennensis* and *Panonychus ulmi* were more than 90% during 20-30d post controlling. 4 The effect of applying *Trichogramma dendrolimi* to apple and pear orchards were 46.7-78.8% to the eggs of *Adoxophyes orana*. 5 The effect of controlling *Carpocapsa nipponensis* by *Steinernema carpocapsae* were 40-80% when 0.075-0.15 billion nematodes/ha. 6 The IPM technology of the pest arthropod in apple orchard that took released and protected natural enemy as the principal thing was given.

22-073

ACHIEVING IMPACT IN STONE FRUIT INTEGRATED PEST MANAGEMENT PROGRAMS IN NEW JERSEY, USA

D.F. Polk, J.L. Frecon, W.P. Cowgill, W.H. Tietjen, D. Schmitt, E.F. Rizio, K.S. Petersen

Department of Agricultural and Resource Management Agents, Cook College, Rutgers University, New Brunswick, NJ USA

A statewide program combined scouting for all arthropods and diseases, nematode detection, and monitoring plant nutrition through soil and leaf tissue analyses. On farm research plots demonstrated mating disruption practices for *Grapholita molesta* (Busck) (OFM) and *Synanthedon exitiosa* (Say) (PTB) and degree day based modeling for *G. molesta* and *Platynota idaeusalis* (Walker) (TABM). Technology was transferred through scouting reports, newsletters, grower meetings, telephone recordings, fax, phone and consultations. Commercial growers producing 65% of the NJ peach and nectarine crop (\$19 million in '95) have enrolled in the program during the last 4 years.

Grower practices included the use of field scouting, threshold levels, alternate middle spraying, biological control of mites, selective pesticides at reduced rates, degree day models, mating disruption, and adherence to fertilizer and nematicide recommendations.

Pesticide inputs varied, but showed overall decreases, especially insecticides. Intensive IPM practitioners saved \$250/ha compared to standard state recommendations. Total farm use of formulated pesticides ranged from 110 kg/ha to 188 kg/ha in 1995. Insecticide use ranged from 11 to 24 kg/ha. Degree day modeling combined with scouting permitted a 40% reduction in insecticide use. Use of mating disruption permitted a 76% reduction in insecticide use from 12.8 kg/ha to 3.1 kg/ha where insecticide was used only for first generation OFM and second generation TABM. Fruit quality averaged over 83% clean fruit.

22-075

APPLE PRODUCTION WITHOUT THE INPUT OF NEUROACTIVE INSECTICIDES

L. Gut, J. Brunner, J. Brown, Washington State University, Tree Fruit Research and Extension Center, Washington, U.S.A.

This was the initial year of a five year comparison of the ecology and economics of Delicious apple orchards managed without using neuroactive insecticides (NNAI) or managed conventionally (CONV). Six orchards were selected for the study, three in northcentral Washington, two in central Washington and one in northern Oregon, U.S.A. Each orchard was divided into a 10-acre CONV block and a 10-acre NNAI block. Pheromones were used as the primary control for codling moth in the NNAI orchards. This treatment alone was as effective as conventional azinphosmethyl sprays at two sites. High codling moth population densities at the other four sites necessitated supplementing the pheromone treatment with two other "soft" controls, mineral oil and parasitoid releases. This combination provided good control of codling moth in two orchards, but greater than 2% codling moth fruit injury was recorded at harvest in the other two NNAI orchards. Adjacent CONV orchards sustained over 1.0% fruit injury at harvest. Most of the codling moth damage in NNAI blocks was found along the orchard edge. Insufficient control of codling moth in NNAI orchards was primarily associated with the inability of selective materials to control border infestations of this pest. Leafroller populations were well controlled in all of the CONV orchards but reached damaging levels in half of the NNAI orchards. Detecting the build-up of leafroller populations in time to control them with *Bacillus thuringiensis* was difficult. Other secondary pests were generally at low levels in NNAI orchards. Natural enemies contributed to the suppression of many of these potential pests. Three species, white apple leafhopper, green apple aphid and tentiform leafminer, reached population densities that required intervention with insecticides in at least one of the CONV orchards. Detailed yield, packout and spray records have been kept for each pair of NNAI and CONV orchards and will be used to compare the economic risks and benefits of these two management programs.

22-076

PESTICIDE-TREATED TRAPS POSSESSING LONG RESIDUAL ACTIVITY FOR CONTROLLING TEPHRITID FRUIT FLIESR. J. Prokopy¹, X. P. Hu¹, B. Shasha² and M. McGuire³

¹ Department of Entomology, University of Massachusetts, Amherst, MA 01003, U.S.A. - ² Biotechnology Research and Development Corporation, Peoria, IL 61604, U.S.A. - ³ USDA/ARS 1815 North Univ. St., Peoria, IL 61604, U.S.A.

Large populations of apple maggot flies (*Rhagoletis pomonella*) have been controlled successfully in commercial apple orchards in Massachusetts (USA) by ringing perimeter-row apple trees with odor-baited sticky (Tangletrap-coated) red spheres that capture immigrating adults before they enter the orchard interior. Sticky-coated spheres are too messy to handle for the large numbers needed for widespread commercial use. Also, sticky spheres require cleaning every 1-2 weeks to maintain capturing power.

We have developed two different types of long-residual-activity pesticide-treated spheres that are equally or more effective than sticky spheres in controlling apple maggot flies and are far easier to handle. The first is a wooden or plastic sphere coated with a mixture of dimethoate (very low dose), sucrose, latex paint and shellac. The second is an inexpensive biodegradable polymeric substance shaped as a sphere, impregnated with feeding stimulant and coated with a mixture of dimethoate (very low dose) and latex paint. This technology is applicable to other forms of traps that could kill tephritid flies that feed on sucrose upon alighting on the traps.

22-078

CONFUSION AMONGST CODLING MOTH FELLOWS CONTINUES: A COMMERCIAL PERSPECTIVE ON THE IMPLEMENTATION OF CODLING MOTH MATING DISRUPTION IN NORTH AMERICAD.R. Thomson

Pacific Biocontrol Corporation, Vancouver, Washington, USA

Mating disruption technology is increasingly being used for the control of codling moth in pome fruit production areas around the world. Some of the countries where codling moth mating technology is used commercially include the United States, Canada, Argentina, Australia, Italy and South Africa. In 1991, Isomate C Plus (Pacific Biocontrol Corp., Vancouver, Washington) became the first commercial formulation of codling moth pheromone to be registered in the United States. The total pome fruit acreage treated with Isomate C Plus has increased from approximately 1,200 hectares in 1991 to approximately 7,300 hectares in 1995. In 1996, Pacific Biocontrol expects to treat in excess of 10,000 hectares.

The successful commercialization of mating disruption technology will depend in large part on the development and implementation of a pheromone-based IPM systems approach. The objective of a pheromone-based IPM program is to effectively manage key and secondary pests in an economically, ecologically and environmentally acceptable manner. In a pheromone-based IPM system, mating disruption is the major tactic used to control the key pest(s). The subsequent reduction or elimination of insecticides for control of the key pest(s) will promote crop or orchard environments that will support higher populations of natural enemies and thus enhance the biological control of both key and secondary pests. The development of monitoring and sampling techniques in conjunction with economic thresholds are essential in order to accurately assess the biological relationships between key and secondary insects and their natural enemies and to implement supplementary controls if required. Pheromone-based IPM should be presented to growers as a long term approach and commitment to pest management. Growers should be encouraged to define yearly objectives and then identify the strategies and tactics needed to achieve those objectives.

TRAPPING-OUT, AN ALTERNATIVE METHOD TO CONTROL APPLE MAGGOT, *Rhagoletis pomonella* (WALSH) (DIPTERA, TEPHRITIDAE) IN APPLE ORCHARDSN.J. Bostanian, C. Vincent & G. Chouinard¹

Agriculture & Agri-Food Canada, Horticultural Research & Development Centre, St-Jean-sur-Richelieu, Québec, Canada
¹ Ministère de l'Agriculture, des Pêcheries et de l'Alimentation, Service de Phytotechnie de St-Hyacinthe, St-Hyacinthe, Québec, Canada.

Trapping-out of apple maggot on an experimental basis has been successful for some time now. The method used is a red sphere alone or in combination with yellow panels. When panels are used, each panel is sandwiched between the two halves of the red sphere. The entire trap is coated with a thin coat of Tangle Trap and baited with a volatile lure. The traps are placed strategically at the periphery of a block (1 to 2 ha) and would intercept any maggots flying into the block. Commercially acceptable apple maggot (~ 1.5% injury) control has been obtained and data will be presented to show this as a control method.

22-079

INSECT VIRUSES AND JUVENIDS DISSEMINATED BY MEANS OF PHEROMONE TRAPS: A POTENTIAL TOOL OF INTEGRATED PEST MANAGEMENT IN ORCHARDSI. Hrdý, J. Kuldová¹, F. Kocourek², J. Beránková², O. Pultar³¹ Institute of Organic Chemistry and Biochemistry, Praha, Czech Republic² Research Institute of Plant Production, Praha, Czech Republic³ Laboratories Biola, Agricultural Cooperative, Chelčice, Czech Republic

The potential of attractant-pathogens and attractant-sterilants in the codling moth, *Cydia pomonella* and the gypsy moth, *Lymantria dispar* control was examined. Males attracted by pheromone into the trap are not killed but contaminated by the biologically active agent. Contaminated males search for females and transfer the pathogen or sterilant to them during copulation. Several designs of codlemone and disparlure baited traps were tested using the method of fluorescent paints. *C. pomonella* granulosis virus (CpGV) and *L. dispar* nucleopolyhedrosis virus were produced at laboratory scale and formulations suitable for coating inside of traps with viral preparations were developed. Field efficacy of traps containing CpGV was examined on three locations. Dissemination of the pathogens in the pest populations was detected by the Elisa test. The juvenile hormone analog W-328 (a carbamate derivative of 2-(4-hydroxybenzyl)-cyclohexanone) was selected for experiments as agent affecting reproduction capability of lepidopteran pests. Sterilizing effect of W-328 when administered to males of *C. pomonella* which were later mated with untreated females was promising (68 per cent of non-hatching eggs). The tested attractant-pathogens and attractant-sterilants are extremely species-specific and ecologically safe and may be useful in situations when the target pest occurs at low population densities.

22-080

THE USE OF PROPARGITE IN INTEGRATED PEST MANAGEMENT PROGRAMS ON APPLES

R.C. Moore, J.C. Graham¹
Uniroyal Chemical Company, Inc., World Headquarters,
Middlebury, CT USA - 1 Uniroyal Chemical Ltd, Kennet House,
Slough, Berks, England

Propargite, one of the world's leading acaricides, is used in over 60 countries on over 30 crops and 30 species of mites. It is a specific acaricide which has been successfully used in Integrated Pest Management programs (IPM) on many crops. When used at recommended rates, propargite is safe to pollinators and to beneficial predaceous and parasitic insects. In addition, predaceous mites will not be eliminated from treated areas. The use of propargite in managing the phytophagous mites, *Panonychus ulmi* and *Tetranychus* spp., on apples in the United States, Republic of South Africa and Australia will be discussed. Examples using propargite to selectively manipulate the predatory mite, *Typhlodromus* spp., and the predatory insects, *Stethorus* spp. in the orchard will be given.

22-082

POSSIBILITIES FOR THE IPM CONFORM USE OF METHIDATHION

B. Sechser
Ciba-Geigy AG, Insect Control, Basel, Switzerland

Methidathion is an organophosphate insecticide with a broad spectrum of activity. In spite of its initial detrimental effect on most beneficials, there are situations in several crops where it can be applied in a relatively harmless way to parasitoids and predators. A full cover spray, five to six weeks after petal fall, in citrus trees against all stages of scale insects provides up to three months of scale control. The subsequent resurgence of scales is largely controlled by reimmigrating parasitoids such as various *Aphytis* species. On pome fruit the product can be applied in a non-disruptive way to beneficial arthropods either as a dormant or delayed dormant spray. For this purpose, methidathion can be mixed with oil. This is common practice for early pest control. Predators and parasitoids tend to appear later than pests and, therefore, have a better chance to survive a methidathion spray.

A good selectivity of a compound against predatory mites is a basic requirement for its use in an integrated system on pome fruit and grapes. Methidathion-resistant strains of *Amblyseius andersoni* have been detected in the field. This resistance was built up by continued application of other organophosphates. A better survival of predatory mites in grapes could be achieved by directing the spray mist selectively to the lower parts of the plants. The survival rate of predatory mites in the upper untreated part with no or few grapes was much higher. From there the predators could reinvade the inferior treated part within a month.

22-081

EFFECTS OF PYRETHROID INSECTICIDE RESIDUES PRESENT ON FRUIT TREE BARK IN CALIFORNIA ORCHARDS

F. G. Zalom, D. Walsh, M. Stimmann¹, C. Pickel², W. Krueger² and R. Buchner²
Department of Entomology, University of California, Davis, CA USA -
1 Department of Environmental Toxicology, University of California, Davis, CA USA - 2 University of California Cooperative Extension, Yuba City, Orland, and Red Bluff, CA USA

Some California almond and stone fruit growers are choosing to use pyrethroid insecticides - either permethrin or esfenvalerate - in the dormant season or during the growing season as alternatives to organophosphate insecticides for control of the peach twig borer (*Anarsia lineatella*), scales, and other insect pests. However, it is not known if they can be used during the dormant season without inducing secondary pest problems, or how long their residues will persist on twigs.

Both permethrin and esfenvalerate were effective in controlling overwintering peach twig borers in the field trials. Results also suggested that the pyrethroid dormant sprays may affect generalist predators, but the impact of this on pest populations could not be determined.

Our laboratory studies indicated that residues of both pyrethroids are almost exclusively associated with the bark, and do not penetrate into the wood. Residues were somewhat more concentrated on node (bud) parts of twigs than on internode areas. If greater concentration of residue is present in the node (bud) parts, predator mites (which overwinter in this area) could have greater exposure to the residue. Pyrethroid extraction from twigs required an organic solvent, and residue could not be efficiently removed by washing twigs sampled from the orchards with either water or water plus a surfactant. From this observation we might assume that rainfall would not remove significant amounts of pyrethroid residue from twigs.

A lab bioassay indicated the amount of residues present on twigs were sufficient to kill the predatory mite *Galandromus* (= *Typhlodromus*) *occidentalis* placed on the bark for as much as 7 months after application of both permethrin and esfenvalerate. Since predatory mites often overwinter on the bark of trees, these results indicate that pyrethroid residues could affect overwintering predator populations.

22-083

Contribution to the control of *Sphaerolecanium prunastri* (Fonsc) on cherry trees in N. Greece.

S S Paloukis & E.I. Navrozidis
Plant Protection Institute of Thessaloniki National Agricultural Research Foundation, 570 01 Thermi -Thessaloniki, Greece.

The bioecology of the scale insect [*Sphaerolecanium prunastri* Fonscolombe (Hemiptera: Coccidae)] was studied from 1993 to 1995 and an effort was made for its control, based on the use of Insect Growth Regulators (I G R.) and winter oils . The results indicate that *S. prunastri* completes only one generation per year. Also, it was found and identified the endoparasite *Coccophagus lycimnia* (Hymenoptera. Aphelinidae) and the predators *Chilocorus bipustulatus* (Coleoptera Coccinellidae) and *Exochomus quadripustulatus* (Coleoptera Coccinellidae). The two years field experiments for controlling the scale revealed that a winter application of paraffinic oil, mineral oil or potassium salt of fatty acids followed by an application in April (I I to I I I nymphal stage) or in July (stage of crawlers) of fenoxycarb, buprofezin and diofenolan gave successful control of the target scale insect and reduced only slightly the parasitization by the endoparasite *C. lycimnia*. However, methidathion which was used in chemical control had a detrimental effect to the endoparasite.

22-084

THE TRENDS OF DIAMONDBACK MOTH PARASITES ON CABAGGE IN RELATION TO DIFFERENT MIXED CROPS. Khuat Dang Long (Institute of Ecology and Biological Resources , National Centre for Natural Sciences and Technology , Nghia Do-Tu Liem-Ha Noi,Viet Nam)

Diamonback moth (DBM), *Plutella xylostella* (L.) is the most important pest on cabbage in Northern Vietnam . The population fluctuations and abundance of the pest were investigated weekly on cabbage (*Brassica oleracea* L. . *B. gongilodes* L.) from November to March of two years 1992-94 . The investigations carried out in two localities of Red River Delta showed that of two important parasites reared from DBM , the pest pupae parasitized by the pupal parasite *Phaogenes* sp. (*Ichneumonidae*) was very low (maximum 3.3%) in comparison with the sole larval parasite *Apanteles* (= *Cotesia*) *plutellae* Kurdj. (*Braconidae*) (average 30.8%) .

It was found that cabbage fields adjacent to maize and rice fields often have significantly lower parasitized pest population by *A. plutellae* than those on cabbage intermixed with different crops of *Solanaceae* ; *Fabaceae* groups and some other decorative flowers (*Asteraceae*) . for the maximal proportion of parasitized pest larvae was less than 25 % (average 13.1 %) on cabbage grown alone compared to percentage of parasitism up to 40 % (average 17.7 %) on the mixed planting cabbage with different crops .

In addition , cabbage fields of both above localities often treated by some pesticides as Cartap (PADAN 95BHN) , Phethoate+ Enthofenprox (CIDI M) but it was observed that peak parasitoid populations usually occurred in the middle and towards the end of the crop .

22-086

DISPERSION PATTERNS OF A MEDFLY POPULATION IN AN HETEROGENEOUS AGRICULTURAL LANDSCAPE D. Nestel, N. Israely¹, U. Kitron², B. Yuval¹

Institute of Plant Protection, Agricultural Research Organization, Beit-Dagan, Israel-1 Department of Entomology, Faculty of Agriculture, Hebrew University of Jerusalem, Rehovot, Israel-2 Department of Veterinary Pathobiology, University of Illinois, Urbana, Illinois, USA

During the last two years we have monitored, with Trimedlure traps, the medfly population build-up and spatial dispersion in an heterogeneous agricultural landscape (2X4 Km) located in the Judean Hills, Israel. The landscape is characterized by patches of different deciduous orchards, typical Mediterranean and forest vegetation and a residential area with home gardens. Adult medflies were not trapped during the winter months, suggesting that they hibernate in this elevation and latitude. During the spring, as well as late autumn, populations were higher in apple orchards. During the summer, the medfly population increases. The spatial dispersion of the medfly in the area is closely related to the seasonal availability of ripe fruit. Abandoned fig trees, which are scattered all around the area, serve as an important source of flies, and as a refugia during the intensive application of insecticides in commercial orchards. Home gardens were also found to contribute to the early build-up of the population and as refugia from pesticide applications.

22-085

PARTITIONING LEAFHOPPER (*ERYTHRONEURA* SPP.) MORTALITY IN CALIFORNIA GRAPE VINEYARDS: INFLUENCE OF GROUND COVERS, PARASITIDS AND SPIDERS (ARANEAE) M. J. Costello, K. M. Daane¹
University of California Cooperative Extension, Fresno, CA USA - 1 University of California Berkeley, Kearney Agricultural Center, Parlier, CA USA

Experiments were conducted in table-, raisin- and winegrape vineyards in the San Joaquin Valley of California to better understand the role of cover cropping, parasitoids and predators as mortality agents of leafhoppers (*Erythroneura variabilis* and *Erythroneura elegantula*) on grapes. Ground covers were a combination of cool season legume/grass mixtures followed by warm season resident grasses. Parasitoids are primarily *Anagrus* spp., which attack leafhopper eggs; spiders (Araneae) comprised over 90% of the predator community.

Leafhopper density in the table grape vineyard was consistently reduced by approximately 25% in the ground cover treatment compared to clean cultivation. This we attribute to higher nymphal mortality because of greater vine stress, as indicated by higher berry sugar levels at harvest and lower vine pruning weights. Neither *Anagrus* parasitism (averaging 30%) nor spider population densities differed significantly between treatments. Compared to the grapevine canopy, spiders in the ground covers were found at low densities and were comprised of a different complex of species. This indicates that ground covers do not provide habitat that contributes to the buildup of spiders on grapevines. Spider species such as *Theridion* spp. were positively associated with leafhopper densities, whereas *Metaphidippus vitis* was negatively correlated. *Cheiracanthium inclusum* was the most commonly sampled spider. An exclusion experiment which decreased spider density on grapevines by 60% increased leafhopper density by 80%.

22-087

EFFECTS OF INTERCROPPING TOMATOES (*LYCOPERSICON ESCULENTUM* MILL) ON THE INFESTATION OF TOMATO FRUIT BORER, *HELI COVERPA ARMIGERA* HUBNER

Shankaraouda Patil, Y.K. Ketikal¹

Department of Olericulture, KRC.College of Horticulture, (Univ. Agri. Sci), Arabhavi Farm - 591 310, Karnataka, India-1 Department of Entomology, KRC. College of Horticulture, (Univ. Agri.Sci.), Arabhavi Farm-591 310, Karnataka, India.

Studies were conducted to assess the effects of intercropping various vegetables in tomatoes on the infestation of tomato fruit borer, *Helicoverpa armigera* Hubner, at KRC College horticultural farm during kharif season 1995. No insecticides were used during the course of experiment. Highest infestation of tomato fruit borer (5.6 percent) was noticed in tomatoes intercropped with snap beans (*Phaseolus vulgaris* L.). Lowest infestation (3.4 per cent) was observed in tomatoes intercropped with radishes (*Raphanus sativus* L.). The fruit borer infestation levels in tomatoes grown alone, tomatoes intercropped with coriander and onion was 4.5%, 4.2% and 4.7% respectively. Greatest reduction in marketable yields of tomatoes was observed in tomatoes intercropped with snap beans followed by tomatoes intercropped with onions. Highest marketable yields was observed in tomatoes intercropped with radishes.

22-088

PREVENTATIVE PEST MANAGEMENT OF *HALOTYDEUS DESTRUCTOR* (TUCKER) AND OTHER EARTH MITES (ACARINA: PENTHALEIDAE) IN AUSTRALIAN RAPESEED

G. McDonald, K. Dunse, and A.A. Hoffmann¹

Plant Sciences and Biotechnology, Agriculture Victoria, La Trobe University, Bundoora, Victoria 3083 Australia -¹ School of Genetics and Human Variation, La Trobe University, Bundoora, Victoria 3083 Australia.

Earth mites (*H. destructor*) and *Penthaleus major* (Dugès) consistently threaten the successful germination and establishment of rapeseed (canola; *Brassica napus*) throughout temperate Australia. The crop is mostly used in rotations and has become one of the most profitable dry-land crops grown. Accordingly, farmers are inclined towards the use of prophylactic insecticide sprays, often applied before germination. The urgency to provide effective alternatives has increased with the recent advent of insecticide resistance in *H. destructor*. There are now good prospects for the use of cultural control to minimise mite impact, through the use of a non-host crop in the previous season, and for the development of resistant varieties.

H. destructor has a wide (apparent) host range, but surprisingly, many of the cereal, pulse and oilseed crops which are known to be susceptible to mite damage are not, in fact, effective hosts. In the laboratory, mite survival and fecundity of these plants was very low. In the field, the pulse crops lupins and chickpeas resulted in extremely low mite populations by the end of the season. Hence these non-host crops may be used in rotation with rapeseed to minimise *H. destructor* populations. The constraints with this approach are that the mites may reproduce on crop weeds or in the microflora on the crop floor; or invade the subsequent rapeseed crop from the borders. A management strategy is proposed.

Despite the relatively narrow gene pool available in the *B. napus* germplasm bank, c. 10% of the lines screened showed some resistance to mite damage when placed under intense, non-choice tests. Some of these lines were derived from seed with low total glucosinolate content. The mode of resistance is being investigated but aliphatic glucosinolates do not appear to have a role.

22-090

RELATIVE SUSCEPTIBILITY OF THREE GRAPEVINE VARIETIES TO INFESTATION WITH *MACONELLOCoccus HIRSUTUS* (GREEN), (HOMOPTERA PSEUDOCOCCIDAE).

A.H. Amin, and A.K. Emam.

Plant Protection Department, Faculty of Agriculture, Ain Shams University, Cairo, Egypt.

Eight morpho-histological characters were used to evaluate the relative susceptibility of three grapevine varieties; moscati, romi and banati to infestation with *Maconellococcus hirsutus* (Green). The four morphological characters were, height of the plant, number & length of internodes, and girth of the stem. The four histological characters were the dimensions of upper and lower epidermis, palisade tissues and spongy tissues of the leaves.

According to the morphological characters of the stem of grapevine, results showed that moscati variety was the most tolerant to infestation, while romi variety was the most susceptible.

According to the histological characters of the leaves and morpho-histological change together, banati variety was the most susceptible followed by romi variety, while moscati variety was the most tolerant to infestation. Therefore it is recommended, that moscati variety be cultivated in the newly reclaimed areas of Egypt.

22-089

A SYSTEM FOR INFECTING THE SWEETPOTATO WEEVIL, *CYLAS FORMICARIUS* (COLEOPTERA:CURCULIONIDAE) WITH THE ENTOMOPATHOGENIC FUNGI, *BEAUVERIA BASSIANA* USING AN IMPROVED SEX PHEROMONE TRAP IN THE FIELD

K. Yasuda

Okinawa Prefectural Agricultural Experiment Station, Naha, Okinawa, Japan

Four strains *Beauveria bassiana* were isolated from sweet potato field Okinawa, Japan. Among them the "Ilatuhiko" strain, separated from the sweet potato weevils (SPWs) collected at Yomitan village, showed the strongest infectiousness in the laboratory. When adults of both sexes were confined in a plastic cup treated with conidia of *B.bassiana*($9.3 \times 10^9/0.1g$), none of them survived. The mean survival period was 8.1 days in the males and 10.5 days in the females, respectively.

The system was consist of a specially designed sex pheromone trap and a holed bottle with the fungus(0.5g), in which attracted male SPWs were infected and went out again. The highest killing rate of males was 96.2% on 21 days after treatment and that of females was 24.0% on 36days in the sweet potato field. Ratio of carrier adults was male:57.9% and female:31.6%. In the treated field, the sex ratio of the SPW population was greatly skewed to the females. Females seemed to be infected through mating with carrier males.

The advantage of the system are:

- 1)High efficiency(attracted males are self-infected with the fungus)
- 2)Species specificity(using sex pheromone)
- 3)The fungus are easy to mass produce
- 4)Low cost compared with the conventional field sprays
- 5)Once attracted and infected males are expected to go back to the habitat, which accelerates dispersal of the fungus.

22-091

EVALUATION OF RESISTANCE TO ALFALFA WEEVIL, *HYPERA POSTICA* (GYLL.) (COLEOPTERA: CURCULIONIDAE) IN NINE ALFALFA VARIETIES

M.Modarres Awal, A. Koocheki¹

Ferdowsi University of Mashhad, College of Agriculture, Plant Protection Department, Mashhad - Iran - ¹ Ferdowsi University of Mashhad, College of Agriculture, Agriculture Department, Mashhad - Iran

Nine alfalfa varieties namely Ramandi, Codi, Bami, Yazdi, Ranger, Hamadani, Simerchenkaya, Maopa and Nikshahri were evaluated in terms of resistance to alfalfa weevil in a complete randomized block with 4 replications. This experiment was repeated for 3 years.

Results showed that there was a rather similar trend in population density associated with adult, larva and pupa number on different varieties. Some varieties showed differences related to biological cycles of alfalfa weevil and thies could be attributed to their relative resistance to this pest. However there was no differences between varieties in terms of their plant component (leaf, stem and flower), despite differences observed in the number of adult, larva and pupa on some of these varieties.

22-092

PROTEASE INHIBITORS EFFECTIVE AGAINST THE BLACK FIELD CRICKET, *TELEOGRYLLUS COMMODUS*, AND PORINA CATERPILLAR, *WISEANA CERVINATA*, PESTS OF WHITE CLOVER

E.P.J. Burgess, W.A. Laing and J.T. Christeller
Horticulture and Food Research Institute of New Zealand Ltd,
Auckland and Palmerston North, New Zealand

Genes encoding protease inhibitors (PIs) which bind with the major proteolytic enzymes of pest insects are being transferred to economically important crop plants to confer insect resistance.

The digestive proteases of an orthopteran and a lepidopteran pest of white clover in New Zealand were characterised and partially purified. A range of PIs were screened *in vitro* to determine their level of binding with these enzymes, and a number of PIs which demonstrated a high level of *in vitro* affinity were incorporated into artificial diet and fed to the insects. Survival, growth rate and levels of activity of digestive enzymes were measured.

Trypsin and elastase were the predominant proteases in the midgut of the black field cricket. Several PIs caused high levels of mortality and reduced growth. The two most effective were POT-2 (from potato) which inhibited both trypsin and elastase and SBTI (from soybean) which strongly inhibited elastase. Combination of POT-1 (from potato) which binds elastase and WGI-1 (from wheatgerm) which binds trypsin) caused a synergistic growth reduction.

Trypsin, chymotrypsin and carboxypeptidase A were the major proteases in porina larvae. BPTI (from bovine pancreas) which reduced digestive capacity to 28% *in vitro* and a carboxypeptidase inhibiting fraction (from potato) both reduced survival and growth rate when incorporated into diet.

Genes for POT-2, POT-1, SBTI and BPTI are now being incorporated into an elite cultivar of white clover for pest resistance.

22-094

INFLUENCE OF BIOCHEMICAL TRAITS OF RAPESEED AND MUSTARD PLANTS ON MUSTARD APHID, *LIPAPHIS ERYSIMI* (KALTENBACH) (HOMOPTERA:APHIDIDAE) INFESTATION

J.S. RANA, K.S. KHOKHAR¹

Department of Entomology, CCS Haryana Agric. University, Hisar, Haryana, India-1 Directorate of Extension Education, CCS Haryana Agricultural University, Hisar, Haryana, India.

The biochemical constituents (Glucosinolates, phenols, sugars and proteins) of *Brassica* cultivars, when analysed showed a differential reaction to mustard aphid infestation. Glucosinolates were found to be imparting resistance in cultivars (RLM-198, RW-29-6, RW-2-2, RH-7846, RH-7847) having high amount of it than those having less such as BSH-1, RW-15-6, RH-8113, Kranti, Krishna, RW-32-2, RK-8602, DIRA-247, PR-8805 and PR-8806. The amount of phenols from various plant parts presented an inverse trend with mustard aphid infestation. However, the high amount of protein and sugars from various plant parts of different cultivars were found to be associated with the susceptibility of the plant to the infestation by mustard aphid.

22-093

EFFECTS OF LEAF COLOR AND EPICUTICULAR WAX ON CEREAL APHID POPULATIONS IN NEAR ISOGENIC BARLEY LINES

S. Moharrami pour, H. Tsumuki

Laboratory of Biological Communication, Research Institute for Bioresources, Okayama University, Chuo Kurashiki 710, Japan

Host plant resistance to the natural infestation of cereal aphid species, especially *Rhopalosiphum maidis* [Fitch] and *R. padi* [L.], was assessed in four marker genotypes of near isogenic barley lines, *Hordeum vulgare* [L.]. Marker genotypes differed in leaf color (normal green and chlorina) and epicuticular wax amount and chemical composition (normal wax and glossy). They were obtained by heterozygous plants for markers and selfed in successive generations up to F₈. Aphid populations were estimated in individual F₈ plants to reveal marker genotype differences.

The aphid densities on parental line E227 (normal type) was significantly lower than that on L118 (chlorina glossy type), indicating that E227 and L118 are resistant and susceptible lines, respectively. Normal plants in color and epicuticular wax were the most resistant type among the genotypes in reaction to high density of aphid species, mainly *R. maidis*. However, the amount of gramine indole alkaloid, known as a deterrent substance, did not confer resistance to aphids in the marker genotypes due to the considerably low level.

22-095

RHIZOBACTERIA-INDUCED CROP RESISTANCE AGAINST INSECT-VECTORED DISEASE PATHOGENS OF VEGETABLES

G.W. Zehnder, C. Yao, J.W. Kloepper¹, J. Murphy¹, S. Tuzun¹, G. Wei¹, R. Shelby¹, O. Chambliss²

Department of Entomology, Auburn University, Auburn, AL USA - 1 Department of Plant Pathology, Auburn University, Auburn, AL USA - 2 Department of Horticulture, Auburn University, Auburn, AL USA

Specific strains of plant growth-promoting rhizobacteria (PGPR) were evaluated in greenhouse and field experiments for control of bacterial wilt of cucurbits, caused by the cucumber beetle-vectored bacterium *Erwinia tracheiphila*, and for control of cucumber mosaic virus on tomato, transmitted in a non-persistent manner by aphids. Treatment of cucumber with PGPR significantly reduced the incidence of wilt disease in plants infected by artificial inoculation and by natural beetle feeding. PGPR-treated plants exhibited reduced concentrations of the beetle feeding stimulant cucurbitacin, and beetle numbers in the field were significantly lower on PGPR-treated plants than on plants treated with insecticide. It is believed that PGPR-induced systemic resistance inhibits the accumulation of cucurbitacin in cucumber by a facultative alteration in metabolic pathway to other plant defense compounds.

In greenhouse experiments, treatment of tomato with specific PGPR strains eliminated or delayed the onset of cucumber mosaic virus symptoms. Results of ongoing experiments to determine PGPR effects on aphid feeding behavior and transmission of cucumber mosaic virus will be discussed.

22-096

**PINK BOLLWORM (LEPIDOPTERA: GELECHIIDAE)
POPULATION REDUCTION IN SHORT-SEASON COTTON
MANAGEMENT SYSTEMS: A CASE STUDY**

C. C. Chu, and T. J. Henneberry

USDA-ARS, Western Cotton Research Laboratory,
4135 E. Broadway Rd., Phoenix, AZ

A cotton management program in the Imperial Valley, CA was specifically designed to reduce pink bollworm, *Pectinophora gossypiella* (Saunders), populations in the area by optimizing the host-free period. The program established 1 March as the earliest planting date, 1 September for defoliant or plant growth regulator application and 1 November for cotton stalk destruction and plowdown. In-season gossypure-baited pink bollworm male moth activity monitoring and immature green cotton boll inspections for larval infestation were encouraged as decision making aids to determine the need for additional control action. Male pink bollworm, moth catches in gossypure-baited Lingren and delta sticky traps were significantly reduced each year from 1990 to 1994 following the initiation of the management program in 1989. Fewer larvae per cotton boll occurred in the years from 1990 to 1992. Fiber quality of commercial cotton sampled was also improved from 1989 to 1994, as compared to the 1984 to 1988 average. Male moth trap catches in gossypure baited traps placed around the perimeter of the Imperial Valley suggest that pink bollworm moth migration into the valley occurred from surrounding cotton growing areas during the growing season. Highest numbers of moths were caught in perimeter traps directionally placed toward cotton growing areas in the Mexicali, Mexico and Bard-Winterhaven and Palo Verde, CA. Cotton production, in general, was reduced during 1989 to 1994 in these areas and may have contributed partially to reduced populations in Imperial Valley, however, yield per hectare was better in 1993 and 1994 as compared to the average yield in 1984-88.

22-098

**INTEGRATED INSECT PEST MANAGEMENT STRATEGIES
FOR COTTON**

B.V. Patil, S. Lingappa, M. Bheemanna, K. Tulsiram
Department of Entomology, College of Agriculture
Raichur-584 101, Karnataka, India.

Four integrated insect pest management (IPM) modules were tested on interspecific hybrid cotton for two seasons at Raichur, Karnataka, India. Ideal IPM module (M1-involving all ecofriendly components), practiceable module (M2-involving components easily available to farmers) and IPM module developed at Raichur (M3-involving bioagents and selective insecticides) were compared for their superiority over recommended plant protection schedule (RPP) (M4-involving only insecticides).

The incidence of sucking pests was least in M4 module and was on par with M3 and M2 module but was highest in M1 module. The activity of parasitoids and predators were noticed in all modules except M4. The number of good opened bolls and cotton yield were highest in M4, followed closely by M3 and M2 modules.

Analysis on the cost effectiveness of modules revealed higher benefits from M3 module followed by M4 and M2 and least in M1 module.

The results suggest that sole reliance on biocontrol agents cannot ensure satisfactory protection to cotton from insect pests.

22-097

**ECOFRIENDLY FORMULATIONS OF INSECTICIDES FOR
SUSTAINABLE INTEGRATED PEST MANAGEMENT IN
COTTON IN TAMIL NADU, INDIA.**

S. Uthamasamy and M. Murugan

Department of Entomology, Tamil Nadu Agricultural University, Coimbatore, India.

Cotton is an important crop grown under varied ecological conditions. Three species of lepidopterous larvae viz., *Earias vittella* (F.), *Helicoverpa armigera* (Hubner) and *Pectinophora gossypiella* (Saunders) damage the squares and bolls. Indiscriminate and unscientific use of bolls. Indiscriminate and unscientific use of chemical insecticides in the last three decades has resulted in environmental problems besides control failure. In the recent past, Integrated Pest Management (IPM) is advocated to sustain the management of pests. Chemical insecticides will continue to play a major role in IPM; however, concerted efforts are made to identify safer and ecofriendly insecticides.

The usefulness of two formulations (Sandoz India - Agrochemicals) of insecticides viz., quinalphos 20 AF (Ekalux 20 AF) and an encapsulated form was studied. Field evaluation of these new formulations along with other insecticides was done with a spray fluid of 200 l/acre using a hand operated sprayer. The results revealed that i) both formulations are effective in reducing the damage caused by larvae of bollworms, ii) the formulations are not toxic to the carnivores inhabiting cotton system (parasitoids, predators such as lady bird beetles and spiders).

The three year study indicates that these new formulations are ecofriendly, fit in the IPM system in cotton particularly with small and marginal farmers.

**IPM ENTRY POINTS, CIBA'S BASIC STEPS TO COMBINE
CHEMICALS, BIOLOGICALS AND MODELLING FOR OPTIMUM
CROP PROTECTION: A CASE STUDY FROM THE VEGETABLES OF
SPAIN**

P.J. Newton, F. Baur, C. Flückiger, J. Ticó¹, M. Fidgett²

Ciba-Geigy AG, Crop Protection Division, Insect Control Business Unit,
Basel, Switzerland - 1 Ciba Agricultura, Barcelona, Spain - 2 Ciba
Bunting Ltd., Colchester, England.

The concept of IPM for more accurate pest management and optimum yield, rather than IPM for less pesticide, is barely touched in the public debate. The perception of IPM fitness in our chemical solutions, or lack of it, only clouds the issue - more energy should be expended now on deriving principles of adequate use for all the solutions in the IPM tool box. This applies as much for established products as for the eagerly awaited pipe-line of new chemistries.

More is required from the agrochemical industry than developing the right products. As Ciba takes its practical implementation of IPM seriously, the focus shifts beyond single-products to the whole crop ecosystem and Integrated Crop Management.

Even the farmers on our European doorstep may be caught up in spiralling pressures to intensify agricultural productivity. For example, although biologically intensive IPM systems are the standard in northern European protected cropping, the rapidly expanding new generation of producers in the Mediterranean Basin rely on chemically intensive crop protection methods in the absence of viable alternatives. Yet, Industry has a clear rôle in promoting the shift to IPM systems which rely on the right balance of available technologies. Identification and exploitation of the IPM entry points is the most effective way to initiate the process.

In this paper we examine a practical example, developed in the farmers' fields of Spain. In a step-by-step process, current Crop Protection inputs have been rationalised in methods that return tangible benefits to farmers; promote the shift to judicious and selective chemical inputs; promote the re-invasion, and intensify the impact, of native natural enemies. Finally, the ground has been prepared for true IPM systems which combine full product ranges of chemical and biological solutions.

22-100

DISTRIBUTION and MANAGEMENT of *FRANKLINIELLA OCCIDENTALIS* (Pergande) IN NEW SOUTH WALES AUSTRALIAG. Herron, V. Rajakulendran, L. Tesoriero A. Cliff

Biological & Chemical Research Institute, NSW Agriculture, Rydalmere, NSW Australia

Frankliniella occidentalis (Pergande) was first found in New South Wales in the Sydney basin (-33° 41', 150° 52'; altitude 19-170 m) during October 1993. It is now well established within the Sydney basin and is present on some properties outside this area. The thrips does not appear to migrate well unaided; most new infestations were associated with the movement of infested material. In the Sydney basin *F. occidentalis* is a pest of both field grown and glasshouse vegetables including lettuce, capsicums, strawberries and Lebanese cucumbers. In contrast to other countries, breeding populations have been found in field lettuce in mid-winter.

The proposed control strategy relies on four factors: 1) restrict the movement of infested material; 2) good hygiene in terms of weed control around the fields, polyhouses and glasshouses; 3) strategic use of insecticides on both weeds and the crop; 4) exploitation of native natural enemies. The most effective registered insecticide is methamidophos, which can be used on weeds and early stages of vegetables and must be sprayed consecutively as three sprays 3-5 days apart. When thrips numbers are reduced, populations can be maintained at low levels close to harvest using other, less potent chemicals with shorter withholding periods. Other insecticides with novel modes of action, including petroleum spray oils (PSOs) are being evaluated. Based on field results for the related species, *F. schultzei*, PSO's may be used as part of resistance management close to harvest to suppress survivors of earlier treatments.

22-102

EFFICACY OF A TRACTOR-PROPELLED VACUUM MACHINE FOR INSECT MANAGEMENT IN POTATO AND CELERY CROPS

P.G. Weintraub, Y. Arazi¹ and A.R. Horowitz

Department of Entomology, Agricultural Research Organization, Gilat Regional Experiment Station, Israel - 1 Research and Development, Sha'ar Hanegev Interprises, Hof Ashkelon, Israel

Over the course of 4 growing seasons, trials were run to evaluate the efficacy of a tractor propelled field-scale vacuum unit for use in insect pest management in potato and celery crops. The vacuum unit was designed to dislodge insects by blowing air from lateral vents onto the plants while simultaneously vacuuming from above. Typically, plots were vacuumed once a week over the course of the growing season. Efficacy was evaluated by yellow sticky traps and hand vacuuming plots before and after the field vacuum. All insects evaluated were effectively removed by the vacuum unit; typically population reductions of 50 - 65% were achieved with whiteflies, leafhoppers, and aphids. In some trials, reductions were achieved which lasted from week to week. Additionally, agromyzid leafminers were significantly reduced in number, but population reductions were temporary because of their strong flying ability. Parasitoids were also effectively removed by the vacuuming procedure but the effect was only temporary. In some cases, pest populations were lower in vacuum treated plots than in insecticide treated plots. There was no adverse effect on potato yield from soil compression.

22-101

AN INTEGRATED PEST MANAGEMENT PROGRAMME FOR CONTROLLING THE LEAFHOPPER *EMPOASCA DECIPiens* (PAOLI) (HOMOPTERA: CICADELLIDAE) ON SUMMER VEGETABLES IN EGYPT

M.K. Hamdy

Department of Pest & Plant Protection, National Research Centre, Dokki, Cairo, Egypt.

On the basis of ecological studies on the leafhopper, *Empoasca decipiens* (Paoli) attacking the vegetables in Egypt, an IPM for controlling it was designed as follows.

1-The highest peak of abundance for the pest population taking place in the last week of May suggested the usage of the chemical control (Tamaron 60% at rate 0.2%) to kill the majority of the pest population. 2-Since the squash plants harbour the highest population compared with vegetables cultivated early in March, and the green-pepper plants similarly harbour the highest population compared with those cultivated lately in mid-June, yet the chemical control should be directed mainly to the both plantations. 3-Regarding the vertical movement abundantly towards the middle parts of the plants at between 10 a.m. and 2 p.m. in May for the early plantations and at between 12 m. and 4 p.m. in August for the late ones, hence the both time periods must be taken properly into consideration when chemical control applied. 4-If the chemical control of May realized the good reduction in the population the late cultivated plants would escape from a severe infestation, if not, the release of the predator, *Coccinella undecimpunctata* Reiche which flourishes during August and July would effect the building up of the pest population. 5-Two additional bio-insecticidal applications, e.g. *Bacillus thuringiensis* Berl. at rate of 250 g./fedden, during the last week of August and in mid-September, respectively will check the weakened remaining individuals of this pest.

22-103

The efficacy of *Aphidius colemani* (Hymenoptera: Aphididae) in combination with an IGR to manage green peach aphid (Homoptera: Aphididae) on chrysanthemumsD. L. Olson, R. D. Oetting

Department of Entomology, The University of Georgia, Georgia Experiment Station, Griffin, GA USA

The Green peach aphid (GPA), *Myzus persicae* (Sulzer), is a highly polyphagous insect that has become an economically important pest of several floricultural crops throughout the US. Growers have relied on chemical insecticides to control this aphid. However, currently most insecticides do not control the GPA at low levels acceptable to growers. In our attempts to reduce this reliance on insecticides, we conducted a series of studies on the impact of *A. colemani* on GPA. This aphid parasitoid alone may not be sufficient to control an aphid population at a level acceptable to growers. Integrating *A. colemani* with Kinoprene, a host specific insect growth regulator (IGR), in an IPM program may be necessary to maintain an aphid population below an economic damage level. Preliminary data indicate that IGRs have little or no detrimental effects on *A. colemani*. Thus, an IPM program combining *A. colemani* with an IGR may have potential to maintain GPA at a level acceptable to growers.

22-104

Susceptibility to malathion of the rose grain aphid *Metopolophium dirhodum* and its natural enemy *Aphidius rhopalosiphii* cultured on susceptible and partially resistance winter wheat varieties.

D.A. Tilahun and H. F. van Emden. Department of Horticulture and landscape, The University of Reading, Reading, United Kingdom.

The intrinsic toxicity of malathion to *Metopolophium dirhodum* and its natural enemy *Aphidius rhopalosiphii* reared on susceptible (Maris Huntsman) and partially resistance (Rapier) winter wheat varieties was determined in the laboratory. Seven different dose levels of 15.625, 7.812, 3.906, 1.953, 0.976, 0.488, 0.244 ppm a.i. malathion were prepared and 0.2 µl applied by topical application to fourth instar aphids and four day old parasitoid. Control insects were treated with 2 µl of the solvent acetone. Dose-response relationships were compared between species using probit analysis and maximum likelihood procedures to determine trends of susceptibility, measured in terms of µg a.i./g body weight.

The bioassay result shows that, dose required to kill 50% aphids on Rapier was six times less than the dose required on Huntsman (i.e. $\log(LD_{50})$ for aphids on Rapier = 0.3672 while $\log(LD_{50})$ for parasitoid = 2.9022 which means to dose required to kill 50% aphid was 8 times less than the dose required to kill 50% parasitoid on Rapier). The slope for aphid on Rapier was steeper than the slope for parasitoid, which means any insecticide reduction against the aphid made by a resistant variety would improve the selectivity of pesticides in favour of the parasitoid.

22-106

INTEGRATED PEST MANAGEMENT OF SOIL INSECTS, AND DISEASES, IN HORTICULTURE

J.N. Matthiessen, J.A. Kirkegaard¹

CSIRO Division of Entomology, Private Bag, PO Wembley, Western Australia, Australia, 6014 - ¹CSIRO Division of Plant Industry, GPO Box 1600, Canberra, ACT, Australia, 2601

Soil-dwelling insects can be severe pests of horticultural crops. Prophylactic treatment using soil-incorporated residual insecticides is now a less accepted control option, but fumigation is rising to take its place in industries that can bear the cost. The suppression of both pest insects and soil-borne diseases is seen as a benefit of this approach and a justification for use of such high-cost agents.

Concern with the longer-term sustainability of such broad-spectrum approaches to control of soil insect pests, and the need to develop lower cost techniques, has directed attention to implementing IPM strategies for their management. A desire to simultaneously control soil-borne diseases in some instances has raised the stakes, and the complexity, for developing IPM systems to achieve such a dual aim.

Improved knowledge of the biology and ecology of African black beetle *Heteronychus arator* (F.) and whitefringed weevil *Graphognathus leucomela* (Boheman) is helping to lessen the severity of management techniques. Unusual biological characteristics of African black beetle are leading to counterintuitive, but effective, treatment with benign insecticides long before the cropping cycle commences. The synthetic fumigant methyl isothiocyanate is highly potent against whitefringed weevil, and an approach being investigated for both insect and disease management is 'biofumigation' with rotational green manure crops that naturally produce various isothiocyanates toxic to both insects and diseases.

22-105

SUITABILITY OF SILAFLUOFEN (MR. JOKER®) FOR INTEGRATED PEST MANAGEMENT (IPM) IN RICE

M. J. Kern, J. Geiß

Hoechst Schering AgrEvo GmbH, Biological Research, H 872, D-65926 Frankfurt/Main, Germany

Research on the selective toxicity between key insect pests and their key natural enemies is advisable for the wise use of insecticides, and it is one way to fully realise pesticide management and integrated pest management (Saito et al. 1991). The sensitivity (LC_{50} -value) of the brown planthopper, *Nilaparvata lugens* (imago) to silafluofen (3.2 ppm) is 40 times higher than for the beneficial wolf-spider, *Lycosa pseudoannulata* (130.2 ppm). The positive ratio of pest versus beneficial is a suitable indicator for silafluofen (MR. Joker®) to be used in IPM-programmes.

Data from silafluofen distribution studies with radiolabelled silafluofen show that after application of 100 g a. i. silafluofen EC20/ha/400 l water, all brown plant hoppers were killed but all wolf-spiders were alive. Furthermore, the uptake of silafluofen/g body weight insect is 2.2 times higher for *N.l.* in comparison to *L.p.* An assessment of the risk concerning silafluofen and *L.p.* shows a safety factor for *L.p.* per daily prey consumption nymphs of 2.5 - 4.8 and for adult *N.l.* of 3.4-5.3 respectively. It can be concluded that hazard to *L.p.* is therefore low.

Furthermore, there is a synergy of *Beauveria bassiana* and silafluofen against *N.l.* In conclusion, silafluofen does not harm the very effective predatory wolf-spider, *Lycosa pseudoannulata* and has the potential for a synergistic effect with the insect pathogen fungus *Beauveria bassiana* to *Nilaparvata lugens*. The new selective chemical silafluofen (MR. Joker®) therefore fits very well in IPM programmes, especially in rice.

22-107

MASS REARING AND QUALITY CONTROL OF LEPIDOPTERAN PEST, *SPODOPTERA LITURA*: PREREQUISITES FOR INHERITED STERILITY PRINCIPLE IN PEST SUPPRESSION

R.K. Seth, Vandana P. Sharma

Department of Zoology, University of Delhi, Delhi, India

An appropriate rearing of large number of insects and their performance at par with those of healthy wild population form the basis of effective utilization of inherited sterility principle, that might be employed with the introduction of mass reared, irradiated substerile *Spodoptera litura* moths into ecosystem having this pest upsurge. A semi-synthetic diet was established to procure viable and similar quality insects. To obtain this, the testing of various combinations of chemical ingredients, ground dry seed source (chickpea, wheat, wheatgerm or soybean), mixed with yeast in an agar base, was carried out. The chickpea based diet was found to be ideal for its further use for mass rearing in the inherited sterility technique, because the growth, development rate, survival were found to be more on chickpea diet than other diets tested. Suitability of the various diets was determined on the basis of an index (adequacy index) incorporating growth, development, fecundity and survival into 1 empirical factor. The chickpea diet's adequacy index was 1.47 after rearing 09 generations and >1.6 after 13 generations (last 4 generations fed on chickpea diet with inclusion of sinigrin as a phagostimulant). This index value is quite comparable to 1.74 as adequacy index on natural food (i.e. castor). Insects reared on the semi synthetic diet and natural diet were tested for their population dynamics. Life tables were constructed. The net reproductive rate (R_0) and intrinsic rate of increase (r_m) of *Spodoptera litura* were ascertained to be 740.23 and 0.2045 on chickpea diet, and 785.20 and 0.2129 on castor leaf, respectively. Mass reared insects on synthetic diet were also tested for mating behaviour (frequency, propensity, nocturnal rhythmicity) and sperm behaviour (production, descent rhythm, spermatophore formation, transfer, storage and competence for fertilization). Their sperm performance was compared with that of normal wild population to understand the moths' potency to be utilized in this control measure.

22-108

THE INFLUENCE OF GAMMA RADIATION ON PEST INSECTS AND USING IT FOR GENETIC CONTROL

M.Kvachantiradze, L.Latsabidze¹, K.Gagoshidze²
Department of Biophysical Methods, Kanchaveli
Georgian Research Institute of Plant Protection,
Tbilisi, Republic of Georgia - 1,2 Same

For the first time in Georgia there have been carried out investigations with a view to develop a genetic method based on the biological action of ionizing radiations of controlling harmful insects. On concrete subjects: Grapholitha molesta Busk., Pieris brassicae L., Lepidotarsa decemlineata Say., and on the basis of a detailed study of life cycle, fertility, polygamy of both sexes, features of food chains, range of migration, and other important biological and ecological aspects of the matter, there have been proven the possibility and advisability of using a genetic method for controlling these pests.

Optimum stage of development, the most sensitive to gamma radiation and at the same time not showing at a high level of sterilization any weakening of important physiological processes, has been recommended for each of the aforementioned species.

22-110

BUILDING SUPPORT FOR INTEGRATED PEST MANAGEMENT: THE EXPERIENCE OF THE SMALL FARMER PROGRAMME OF THE CIBA'S CROP PROTECTION DIVISION.

X.Ledru, J. Bandonj¹, M. Hiller², Marjudin Kusnawiria³
Ciba-Geigy AG, Crop Protection Division, PP 7.34, Basle, Switzerland
1 Ciba-Geigy (Phils.) Foundation Inc., Manila, Philippines
2 Ciba-Geigy Colombiana, Crop Protection Div., Bogota, Colombia
3 PT Citraguna Saranatana, Jakarta, Indonesia

As stated in its charter, the Crop Protection Division of Ciba regards Integrated Pest Management (IPM) as the most efficient crop protection method leading to sustainable agriculture. Therefore, it designs programmes for an IPM compatible use of its products and provides appropriate information, advice and training to its customers.

The Small Farmer Programme co-ordinated by the Farmer Support Team (FST) aims at improving small-scale farmers' pest management skills. It started in 1992 in 10 pilot programme areas in countries located in Latin America, Africa and Asia. The IPM strategy currently implemented in the Small Farmer Programme comprises three areas of activities: Prevention / Observation / Intervention. Some examples are presented. The support the FST provides to farmers for the extension of IPM goes beyond pesticide use, it includes other elements for instance agronomic practices.

The result of the FST activities has been an optimisation of pesticide usage among trained farmers. This IPM oriented strategy is a contribution toward Sustainable Agriculture because:

- It increases the skills of farmers in Crop Management
- It increases the quality and the quantity of the produced crops
- It reduces the environmental impact of Pest Control Activities

22-109

PERTINENCE OF SPERM STUDIES IN F-1 STERILITY TECHNIQUE : A SPECIFIC MODALITY IN MANAGEMENT OF LEPIDOPTERAN PEST, SPODOPTERA LITURA (FABR.)

R.K.Seth

Department of Zoology, University of Delhi, Delhi, India

Need of F-1 Sterility Principle to be employed in the suppression of Lepidopteran pest, Spodoptera litura was felt due to limitations in direct use of Sterile Insect Technique owing to the peculiar feature of high radio-insensitivity of this moth. Evaluation of a substerilizing gamma dose range (40-200Gy) was done to ensure involvement of increased percentage of treated moths, that would be more competitive in mating, in reproductive act. This caused production of survivors in the first filial generation (i.e., F-1), and their inherited sterility (manifested due to aberrations/heterologous translocations in holokinetic chromosomes) was noticed as latent but bonus effect which could be effectively utilized in pest control. Operation of the F-1 sterility principle seems to depend upon (i) P-1 adult behaviour, (ii) P-1 sperm behaviour, (iii) F-1 progeny development, (iv) F-1 adult behaviour, (v) F-1 sperm behaviour. The sperm complement in the spermathecae of females, mated with P-1/F-1 moths, must be optimal (in terms of quality and quantity) to prove sperm competence, and the utilization of genetically altered sperms must occur for fertilization with normal ova, so as to fulfil the aim of F-1 (inherited) sterility technique, i.e. the reproductive interaction of treated insects and their progeny with the natural population of this pest moth for its eventual suppression by producing inviable zygotes. Behaviour of substerile P-1 moths influenced the F-1 progeny, and adult (P-1/F-1) behaviour contributed to sperm behaviour. Sperm behaviour was found to be an integral component for quality of insects and it acted as a decisive factor in F-1 sterility principle. Detailed studies were carried out, in irradiated P-1 insects (100Gy & 130Gy), their F-1 progeny and normal Spodoptera litura, on the formation of both types of sperm (eupyrene and apyrene), their descent rhythm (from testes to seminal vesicle and ejaculatory duplex), sperm transfer (from male to female, within female), and finally amphimixis of eupyrene spermatozoa genome with female gamete genome.

22-111

DEVELOPMENT OF COMMODITY-SPECIFIC DEFINITIONS OF I.P.M. AND THEIR USE IN COST-SHARING AND MARKETING PROGRAMS IN MASSACHUSETTS, USA

W.M. Coli and C.S. Hollingsworth

Dept. of Entomology, University of Massachusetts, Amherst, MA USA

General definitions of Integrated Pest Management (IPM) have proven to be of limited value as the basis of cost-share programs designed to encourage grower adoption of IPM. In addition, U.S. environmental and consumer groups have questioned the reported environmental benefits of IPM, given uncertainty as to which specific practices constitute an IPM system for a given crop. Further, Massachusetts farmers have indicated that one of their principal perceived benefits of IPM, is to improve public perceptions of local agriculture. Because improved perceptions could potentially increase crop prices and/or market share of consumer food dollars, farmers have requested a means to be recognized in the marketplace as IPM practitioners.

With these facts in mind, in the late 1980's, an interdisciplinary group of scientists in Massachusetts attempted to fully describe IPM systems then ready for implementation on several important crops: apples, cranberry, cole crops, potato, strawberry, and sweet corn. Growers, private IPM consultants and other agency representatives also participated in the process. IPM practices for each crop were grouped under general categories, such as Soil and Nutrient Management, Insect Management, Disease Management, etc., and point values assigned to specific practices based on their importance and difficulty to implement.

Information is presented on how these definitions, referred to as Commodity-Specific IPM Guidelines, have facilitated growth of a USDA cost-sharing program (SP-53), and have formed the basis of a first of a kind IPM marketing program known as Partners With Nature. The latter, developed in collaboration with the Mass. Department of Food and Agriculture, has generated substantial favorable publicity for participating growers, and has the potential to become regional, based on interest and support expressed by a well-known consumer advocacy group.

22-112

MANAGEMENT SAMPLING FOR LARVAE OF THE COLORADO POTATO BEETLE, *Leptinotarsa decemlineata* (SAY) (COLEOPTERA: CHRYSOMELIDAE)

N.J. Bostanian, M.R. Binns¹ and G. Mailloux²

Agriculture & Agri-Food Canada, Horticultural Research and Development Centre, St-Jean-sur-Richelieu, Québec, Canada 1) Agriculture & Agri-Food Canada, Statistical Research, Ottawa, Ontario, Canada; 2) Ministère de l'Agriculture, des Pêcheries et de l'Alimentation, Service de Phytotechnie de St-Bruno, St-Bruno de Montarville, Québec, Canada.

Untreated plots of 'Kennebec' and 'Superior' potatoes were sampled for Colorado potato beetle larvae at l'Assomption, Quebec, in 1982, 1986 and 1987. Beetle larvae per stalk were counted on 74 occasions for sample sizes ranging from 50 to 200 stalks. Regression techniques were used to estimate the relationship between mean and cumulative proportion of infected stalks. These were used to set up binomial sequential probability ratio test sampling plans for pest management decision making with tally numbers equal to 0, 1, ... 10. A binomial scheme defined by tally number equal to 4 is proposed for general use and corresponding plans are given, with operating characteristic and average sample number curves.

22-114

MANAGEMENT STRATEGIES FOR *IRIDOMYRMEX* SPP. (HYMENOPTERA: FORMICIDAE) IN AUSTRALIAN CITRUS GROVES.

M. M. Stevens, D. G. James

Yanco Agricultural Institute, NSW Agriculture, Yanco, Australia

Ants, particularly *Iridomyrmex* spp., interfere with the biological control of honeydew-producing insects (soft scales, aphids, mealybugs and whiteflies) in Australian citrus orchards. Excluding ants from tree canopies leads to higher predator and parasitoid populations, reduced numbers of honeydew producers, and less downgrading of fruit due to sooty mould contamination.

Trunk barriers, although labour-intensive to apply and maintain, are one option for *Iridomyrmex* control. Long-term efficacy of tested barriers was highly variable. Chlorpyrifos (Super-IQ^(R) 0.9% active w/v) and lambda-cyhalothrin (Karate^(R) 0.6% active w/v) painted on trunks were relatively ineffective. Alphacypermethrin-treated AntCaps^(R) provided control for one season (7 months), whilst chlorpyrifos-impregnated ribbon barriers (14% active w/w) have, to date, excluded ants from tree canopies for 27 to 33 months.

Baiting represents a potentially more cost-effective strategy for ant control. A commercial hydramethylnon bait, Arinosu-Koroni^(R), suppressed *I.rufoniger* gp spp. for up to 75 days (10 g bait/tree, 0.88% active w/w). The effect of Arinosu-Koroni^(R) on *I.purpureus* (F.Smith) depends on nest size; 10 g bait/nest eliminated foragers for at least 91 days on small (1 sq. metre surface area) nests, but had no effect on large (4 sq. metre) nests. Studies on seasonal foraging activity indicate that baiting programs should be initiated in late September to early October in southern New South Wales.

22-113

Integrated control of important pests of pomegranate in Varamin

By

Dr. A. Mirkarimi, Aboureyhan institute of Higher Education

In an integrated control program for important pests of pomegranate, Physical, Mechanical, Chemical and biological methods is applied against important pests such as Carob moth, Aphids, spider mites, white grubs and wood and twig borers in Varamine. For this purpose decaying fruits were collected and destroyed in the winter, late dormant spray with winter oil, insecticide application in the soil for white grubs were used - Trichogramma egg parasitoid applied as biological control methods, the results will be shown with the statistical analysis film strips and photographs.

22-115

INTEGRATED PEST MANAGEMENT IN SORGHUM, *SORGHUM BICOLOR* (L.) MOENCH IN RAJASTHAN STATE.

L.S. Sharma, T. Hussain

Department of Entomology, Rajasthan Agricultural University, Rajasthan College of Agriculture, Udaipur - 313 001, India.

Sorghum is an important food and fodder crop. East and south east Rajasthan is the chief sorghum growing area. Insect pest damage is a major constraint in sorghum production. Therefore, IPM is necessary. Entries have been screened against shootfly as well as stem borers. In shootfly 'dead hearts' percentage was the main criteria while in stem borers, leaf injury, dead hearts and tunnel length were the main parameters. The entries were found promising for both the insects viz., SPV-462, SPV-673 and ICS 4B. Crop sanitation, removal of stubbles reduced the borer infestation. Sowing along with monsoon minimise shootfly infestation. In delayed sowing soil treatment with carbofuran 3G. and phorate 10 G. @ 3.0 g and 1.5 g per meter row length respectively minimise the shootfly infestation (1.67 per cent). Whorl application of carbofuran 3G. @ 8 and 10 kg/ha on 25th and 35th day after germination, respectively reduce the borer infestation (2.95 per cent). Release of egg parasitoid *Trichogramma chilonis* in combination with carbofuran + High seed rate also lowers the shootfly infestation.

22-116

CHARACTERISTICS OF ECOSYSTEM AND IPM SYSTEM ON TEA PLANTATION IN JAPAN

Akira Kawai

Department of Tea Agronomy, National Research Institute of Vegetables,
Ornamental Plants and Tea, Kanaya, Shizuoka, JAPAN

Since tea plant is perennial and evergreen, most insect pests and their natural enemies inhabit in tea plantation through the year. The management of tea plantation including insecticide application is mainly conducted on the plucking surface, and the effect of the artificial management is very small against the bush below the plucking surface. Ecosystem of tea plantation is one of the most complex agro-ecosystem. The bush below the plucking surface is important as the refuge for natural enemies, and natural enemies well control the population density of insect pests infested on mature leaves even under the insecticide application. For example, *Amblyseius wormsleyi* well controls the population density of *Tetranychus kanzawai* which is one of the most important pests of tea plant. However, biological control of insect pests infested on new shoots is difficult and insecticide application is necessary for these pests. Moreover, *A. wormsleyi* developed insecticide resistance for various kinds of insecticide. Considering these characteristics of ecosystem of tea plantation, the IPM system is proposed. In the system, both natural enemies and insecticides are used complementally. Insecticides are mainly used for the pest on new shoot and in early summer, and natural enemies well control the pest on mature leaves and in other seasons.

22-118

CHANGES OF PEST AND ARTHROPOD COMMUNITY COMPOSITION AFTER INTRODUCTION OF IPM IN APPLE ORCHARDS

E. Kocourek¹, J. Berankova¹, V. Jarosik², J. Kinkorova¹

¹ Research Institute of Plant Production, Praha - Ruzyně, Czech Republic

² Faculty of Sciences, Praha, Czech Republic

Integrated pest management (IPM) was introduced at 1 ha apple (cv. Idared) orchard in central Bohemia, and compared with an orchard under classical chemical control. Phenology and population dynamics of pest and beneficial arthropods was investigated by several methods including limb jarring, sweeping, pheromone and pitfall traps, and visual counts.

Seven of 15 important pest species were more abundant (e.g. *Anthonomus pomorum*, leafminers, leafrollers), and 8 pest species were less abundant (e.g. spider mites, *Cydia pomonella*, *Hoplocampa testudinea*) in the IPM than in the classically managed orchard. Diversity of the phytophagous community and abundance of several herbivorous species (mostly indifferent) increased following introduction of IPM. The changes in abundance were specific for different taxonomic groups and varied with their trophic specialisation.

The number of pesticide applications decreased in the IPM orchard. An analysis of the inputs and yields revealed a positive economic effect of introducing IPM (compared to classical control). This appeared due to increased yield in spite of minor decrease of product quality.

22-117

VEGETABLE IPM RESOURCES AND DELIVERY FOR NORTH CAROLINA GROWERS

K. A. Sorensen

Department of Entomology, North Carolina State University,
Raleigh, NC USA

Insects threaten efficient vegetable production and markets by lowering yields, reducing fruit quality, and making harvests unreliable. Vegetable grower IPM technology includes development and availability of information, efficient delivery and application, supportive research and extension that helps people put knowledge to practical use. Grower risks include cost of control, applications of unnecessary sprays and critical decision making process.

Insect identification and recognition of damage is the first step in IPM. North Carolina State University has a Plant Disease and Insect Clinic that serves grower and homeowner concerns and trains agents and students. Over 40 counties in North Carolina have received training, equipment and supplies, and have County Plant Clinics.

The Insect and Related Pest Manual Series is an excellent resource on insect stages, biology and management. Some 50 Vegetable Insect Notes offer additional training material and handouts on selected pests.

Know and Manage Pest Posters combine insects and diseases and provide an effective visual tool for quick recognition and selection of various management strategies and tactics.

Related resources include publications, On Farm Tests, site visits, slide set/scripts, videotapes, control recommendations, etc. Training centers on N.C. Agricultural Chemical School, N.C. Vegetable Expo, Annual Extension Conference, Agent Share Session/Workshop, field days and tours.

Delivery is via written word (annual reports, publications, insect notes), electronic mail, voice mail, newsgroups, Teletip, mobile phone, radio and through distance education.

22-119

STUDIES ON THE IPM OF POPLAR HIGH-YIELD AND QUICK GROWING PLANTATION

Ai-li Zhang

Shenyang Forest Pest Control and Quarantine Station, Shenyang, Liaoning Province,
China.

There are five main insect pests (*Cryptorhynchus lapathi*, *Paranthrene tabaniformis*, *Saperda populnea*, *Coccus mongolicus*, *Maladera orientalis*) on poplar high-yield and quick growing plantation in Liaoning Province.

We studied their life-histories, best control time and best control insect stages by using light traps, sex pheromones, accumulated temperature analyses, etc. Forest management measures include seedling quarantine; spreading strip mixed by Cathay poplar and Black poplar groups; trimming off dead branches. Biocontrol measures include attracting adults of *Paranthrene tabaniformis* with sex pheromones and protecting and utilizing insectivorous birds. Chemical control measures include smearing insecticide rings and spots and stopping up pest hole with aluminium phosphide. Because of the best work programs have been selected and the insecticide application equipments have been improved, the work efficacy is raised for 3-4 times and the costs are reduced. The total control result is raised from 73% to 94%. The size of stand which have been controlled increased 3.6 times when compared with the untreated stand.

INTEGRATED PEST MANAGEMENT IN APPLE ORCHARDS.
EXPERIMENT IN ROMANIA

T.Baicu¹, A.Serboiu², G.Margarit¹, M.Stanculescu¹
1 - Research Institute for Plant Protection, Bucharest,
Romania; 2 - Research Fruit Tree Station - Volnesti,
Romania

The experiment within the IPM project was organized at the Fruit Tree Research Station, Volnesti, in a 2 ha old orchard (26 year) and in a new orchard planted in 1994 (2 ha), half with cvs Generos and Florina, resistant to apple scab.

Buckwheat (*Fagopyrum esculentum*), dill (*Anethum graveolens*), sorghum (*Sorghum bicolor*), vetch (*Vicia sp.*) and coriander (*Coriandrum sativum*) were undersown along the tree rows.

Comparison between the IPM system and chemical supervised control in the old orchard was favourable to IPM. Fruit quality was slightly superior in the chemical supervised control plot. The amount of beneficial fauna was much higher in the IPM plot. The number of sprayings was reduced in the IPM plot to 12, compared to 16 in the supervised control plot.

In the young orchard with resistant cvs superiority of IPM was demonstrated by a low number of sprayings, low amount of active ingredient per hectare (3.18 kg/ha a.i. instead of 10.64), as well as a good activity of beneficial arthropods.

22-122

COMPREHENSIVE MANAGEMENT TECHNIQUE OF TETTIGONIELLA VIRIDIS(L)
Wang Ai jing(Xinjiang Academy of Forestry Urumqi, 830002, China)

Tettigoniella viridis(L) is very popular in Chinese farming and forestry. The host plants are amount to 39 families, 102 genus and 166 species. Among them, the gardens plants reach more than 30 species.

In Xinjiang province the pest breaks out twice every year. the hibernating hatching ova accumulated temperature is higher than 0°C reaching more than 400°C. The raging period of incubation of hibernating ova of the pest coincides with phenological phase of pear blossoms being out. The raging period of oviposition, in autumn coincides with phenological phase of oleaster ripeness being out. Interval between the mass appearance of first generation of the adult and the raging period of oviposition is about 30 days. It is worked out that Control index of the pest, to one-year and two-year poplar trees is 20-25egg lumps/0-50cm. branch 11-14 adult pests per-tree.

The pests egg-lump distribution belongs to assembly distribution.

The integrated Control measure is joint defence by agriculture and forestry. It includes Weeding, killing ova pruning branches infested with pests. Combined with selecting pestresistant tree species such as populus italica. The Categories reach to 66 species. luring adult pests to their death with black light. protecting *Allothrombium pulvinum* E. and other six species of natural enemies spraying with 2.5% Leltamethrin milk oil to Control the adult pests.

22-121

INFLUENCE OF DIFFERENT SOURCES OF
PHOSPHORUS IN MAIZE (*Zea mays* L.) ON THE *Spodoptera frugiperda* (J.E. SMITH, 1797) DEVELOPMENT.

J.F. Grana Jr., L.A. Valério, C.H.C. Conceição, M.H. Calafiori, J.L. Florcovski

Departamento de Fitotecnia. Faculdade de Agronomia "Manoel Carlos Gonçalves". Espírito Santo do Pinhal - SP. Brazil

The influence of different sources of phosphorus in maize affecting *Spodoptera frugiperda* development was observed in Faculty of Agronomy "Manoel Carlos Gonçalves" - Espírito Santo do Pinhal - São Paulo. The cultivar Dyna 170 was grown in greenhouse conditions. The insects were fed with maize in laboratory at 26° C and 12 hours of light.

The treatments arranged in a complete randomized design with 8 replications were : A- control; B- NK; C- NPK (single superphosphate); D- NPK (triple superphosphate); E- NPK (phosphate rock); F- NPK + P (double dosage of single superphosphate); G- NPK + P (double dosage of triple superphosphate); H- NPK + P (double dosage of phosphate rock). The treatments were based upon soil analysis.

Length, weight of larva and pupa, larval and pupal period were evaluated.

The lack of fertilization and phosphate rock application induced to the least length, weight of larva and pupa and also to a minor pupal period. The larval period was the greatest with phosphate rock. The parameters evaluated were greater with single and triple superphosphate excepting to larval period.

22-123

INTERCROPPING AS A PEST MANAGEMENT STRATEGY
AGAINST CARROT FLY (*PSILA ROSAE* F.)

B. Rämert

Swedish University of Agricultural Sciences Horticultural Research station Uppsala Sweden

Intercropping of carrots and lucerne, *Medicago littoralis* Rohne ex Loisel. was found to be effective in reducing intensity of carrot fly damage. The studies were carried out during 1988-1994. The mechanisms operating in the intercropping system were studied. The influence of natural enemies and the importance of carrot fly host-finding behaviour were studied. However, there was no correlation between the amount of predators (staphylinids, carabids and spiders) and damage level of carrot fly. In an experimental study densities of polyphagous predators were enhanced and decreased. A significant differences in damage between the monocultural and intercrop treatments was found, however, irrespective of predator density. The importance of an intercrop for host-finding behaviour was tested by measuring the number of flies in monoculture and intercrop with lucerne in field experiments arranged in three different ways. More flies were caught in the monoculture treatment than in the intercrop, when plots were placed next to each other or placed apart from each other surrounded by ley. However, no differences were found between treatments when plots were apart and surrounded by bare soil. Nevertheless damage levels were always lower in the intercrop treatment. In greenhouse experiments egg deposition by the carrot fly was lower in intercropping.

The yield decrease due to competition from the intercrop was quantified and assessed with respect to the benefits of the intercrop in terms of reduced damage from the carrot fly, soil nitrogen enhancement through N-fixation, and decreased weed germination and development.

22-124

LONG TERM EFFECT OF RATES OF INSECTICIDES AND REFUGIA UPON NATURAL ENEMIES OF SOYBEAN PESTS.

I. C. Corso, D. L. Gazzoni

National Soybean Research Center, Brazilian Agricultural Research Enterprise (CNPSo/EMBRAPA), Londrina-PR, Brazil

A field experiment was conducted at CNPSo/EMBRAPA experimental station, during the 1992/93 soybean season, aiming to evaluate the impact of insecticides, with different schemes of application, on predators and parasitoids of soybean pests, along all the soybean cycle. Experimental design used was random block, with three replications, and plots measuring 20x70 m. The treatments consisted of two insecticide applications (velvetbean caterpillar / stink bug control). Insecticides and rates used were: a. *Baculovirus anticarsia* 20 g pc.ha⁻¹/endosulfan 219 g ia.ha⁻¹ + NaCl 0,5%; b. endosulfan 175 g ia.ha⁻¹/endosulfan 438 g ia.ha⁻¹; c. lambda-cyhalothrin 3.75 g ia.ha⁻¹/lambda-cyhalothrin 7.5 g ia.ha⁻¹; d. monocrotophos 80 g ia.ha⁻¹/monocrotophos 150 g ia.ha⁻¹; e. *B. anticarsia* 20 g pc.ha⁻¹/monocrotophos 150 g ia.ha⁻¹; f. *B. anticarsia* 20 g pc.ha⁻¹/monocrotophos 100 g ia.ha⁻¹ + NaCl 0,5%, applied on strips of 1.5 m spaced by 1.5 m without insecticide; g. profenophos 80 g ia.ha⁻¹/monocrotophos 100 g ia.ha⁻¹ applied on strips of 3m spaced by 3m without insecticide; and h. check. The shock method was used to evaluate the insect population, collecting dead insects fell on a ground cloth after 15 minutes. The insects collected on the samples were identified and counted on the laboratory. Statistical analysis did not indicate differences among the treatments relating to number of individuals of each major predators or parasitoids species, or even when grouped by family, order or feeding habit. The major number of Diptera and Hymenoptera specimens were consistently collected on plots where monocrotophos was sprayed.

22-126

INDIVIDUAL EVALUATION OF RICE RESISTANCE TO THE GREEN RICE LEAFHOPPER, *NEPHOTETTIX CINCTICEPS* UHLER (HEMIPTERA: DELTOCEPHALIDAE)

M.Hirae, S.Oya, K.Tamura, Y.Fukuta

Hokuriku National Agricultural Experiment Station, Joetsu, Niigata, Japan

Accurate and rapid technique to evaluate individual level of resistance for genetic analysis was established. Resistance of eighty B₁F₁ plants, from the cross between resistant Norin-PL6 and susceptible Toyonishiki, was evaluated by two methods: seedling test and leaf blade test for antibiosis. In the seedling test, five newly hatched nymphs were caged with one seedling at the first-leaf stage in a test tube. Nymphal survivorship and stage were recorded after 3-4 days. We could not find a clear segregation because of continuous distribution using only survivorship. However, the segregation of B₁F₁ plants was clear using two indices: nymphal survivorship and stage. In the leaf blade test, the result was similar in the seedling test using two indices. Genetic analysis of resistance using individual test and molecular markers (restriction fragment length polymorphism) indicated that the resistant genes for green rice leafhopper located on chromosome 3 and chromosome 11 in Norin-PL6.

22-125

MECHANISMS OF GROUND COVER EFFECTS ON *ERYTHRONEURA VARIABILIS* AND *ERYTHRONEURA ELEGANTULA* (HOMOPTERA: CICADELLIDAE) IN CALIFORNIA VINEYARDSR. Hanna¹, F. G. Zalom¹, L. E. Williams¹, E. A. Weber²¹Departments of Entomology and Viticulture & Enology University of California, Davis, CA USA- ²University of California Cooperative Extension, Napa, CA USA

We have conducted several large and small scale experiments to determine the effect of ground cover management on two species of leafhoppers, which are serious pests of grapevines in California vineyards. Ground covers consisted of fall-planted grass and vetch mixtures that were either plowed down in mid-spring or early summer. Leafhopper infestations were reduced substantially in some vineyards in the presence of vegetative ground cover. Generally, leafhopper numbers were lowest in the early-summer plow down, intermediate in the mid-spring plow down, and highest in the bare-ground plots. The underlying mechanisms behind these observations were site-specific. On 'Thompson Seedless' grapevines in the San Joaquin Valley, lower leafhopper densities were caused by higher densities of spiders and probably non-host interference by the ground cover. Differences in vine-nutrient and vine-water status were not important. On 'Sauvignon blanc' grapevines in the Napa Valley, lower leafhopper densities were associated with greater water and nitrogen stress. Spiders in the young 'Sauvignon blanc' vineyard were very low on all vines and were not affected by the presence of ground cover.

22-127

MECHANISM OF RESISTANCE TO THE GREEN RICE LEAFHOPPER, *NEPHOTETTIX CINCTICEPS* UHLER (HEMIPTERA: DELTOCEPHALIDAE) AND SUPPRESSION OF THE LEAFHOPPER POPULATION IN THE FIELDS IN THE PARENTAL AND BREEDING LINES OF RICE

S. Oya, M. Hirae, K. Tamura, Y. Fukuta

Hokuriku National Agricultural Experiment Station, Joetsu, Niigata, Japan

Green rice leafhopper (GRLH) is an important insect pest of rice in Japan. To use the resistance of rice for integrated pest management in GRLH, screening on resistance has been conducted in Japan. Several Indica varieties showed considerable resistance, while all Japanese varieties were susceptible. We tested the resistance of 4 parental lines and 5 breeding lines to the GRLH in laboratory and field conditions. The resistance genes of these lines are derived from Indica varieties. A high nymphal mortality was observed on most of the parental and breeding lines at early tillering stage. In contrast, a few breeding lines showed moderate resistance to the GRLH. The egg production was reduced to 4/10-7/10 on these breeding lines, as compared with susceptible varieties. On the other hand, all the parental and breeding lines were less preferred by the female adults. The population density also remained significantly low both in the parental and breeding lines, while the density increased in the susceptible varieties. These results suggest that the mechanism of resistance resulting in the suppression of the GRLH population in the fields is associated with non-preference and antibiosis. This indicates a possibility to use the moderate resistant breeding lines for IPM in the GRLH in Japan.

22-128

RESISTANCE OF SOME PEAR GENOTYPES TO PEAR PSYLLA PSYLLA PYRI L.

S. Milenković, S. Stamenković

ARI "Serbia", Fruit and Grape Research Centre, Čačak Yugoslavia

Pear psylla (*Psylla pyri* L.) is a major pest in the plantation orchards in Yugoslavia. Insecticides have been mostly used in the control of this pest so far. The paper presents the first obtained results of the study on resistance of some pear cultivars to pear psylla.

The investigations were conducted in varietal plantings of the Fruit and Grape Research Centre, Čačak over the 1991-1994 period.

The criteria for resistance evaluation were grouped as follows: parameters of population dynamics of pear psylla and parameters of damage degree (defoliation, honeydew and sooty mould).

The tests included 20 pear cultivars. Moderate resistance was shown by three cultivars (Magness, Karamanka and Vidovača).

These cultivars should be used for breeding other resistant cultivars due to their good pomological properties.

22-130

MOLECULAR BIOLOGICAL AND GENETICAL ANALYSIS OF THE EFFECTS OF RADIATION AND RADIOISOTOPES ON INSECT STERILITY

Judy Ju-Hu Chiang¹, Robert K.C. Chen², Abraham S.K. Chen³

Department of Entomology National Chung-Hsing University Taichung Taiwan R.O.C. -1 Department of Environmental Engineering National Chung-Hsing University Taichung Taiwan, R.O.C. -2 Department of Entomology National Chung-Hsing University Taichung Taiwan R.O.C. -3 Department of Entomology National Chung-Hsing University Taichung Taiwan R.O.C.

In the sterilization of male insect by irradiation the important function is to obtain a genetic dominant lethal mutation. Pupae of insect were treated with radiation, the organelles in the germ cell showed damage, which may be used to produce the sterile male insect. Radiation must be given before meiosis in order to produce mutant. Insects were fed on radioactive diets. Changes of the structure of the organelles in germ cell and adverse effects on fertility are examined. The chromosome became aberration will bring about the decrease of propagation ability. The damage to centrioles is associated with loss of sperm activity. The damage to mitochondria is associated with abnormal insect development. The damage to lysosome is believed to be responsible for destruction of protein. Spermatocytes were examined by the light microscope and transmission electron microscope. Proteins, amino acids, and peptides were analyzed by electrophoresis.

22-129

DETERMINATION OF ANTIBIOSIS AND ANTIXENOSIS TO *ALABAMA ARGILLACEA* (HÜBNER) AND *HELIOTHIS VIRESCENS* (F.) (LEPIDOPTERA: NOCTUIDAE) IN COTTON GENOTYPESG. Contreras¹, G. Videla¹, J. Poissón², M. Polak¹, A. Ruiz¹¹ Departamento de Entomología, Instituto Nacional de Tecnología Agropecuaria, Sáenz Peña, Chaco, Argentina² Departamento de Genética, Instituto Nacional de Tecnología Agropecuaria, Sáenz Peña, Chaco, Argentina

Ten genotypes (three cultivars and seven advance lines) were tested to determine types of resistance to *Alabama argillacea* (Hübner) and *Heliothis virescens* (F.) in both lab and semi-field conditions, in Chaco, Argentina, during 1995. Insects used in the experiments came from rearing facilities ($25 \pm 3^\circ\text{C}$, $60 \pm 10\%$ RH, 14:10 L:D).

Antibiosis was evaluated feeding neonate larvae of *A. argillacea* and *H. virescens* with cotton leaves and squares, respectively, of each genotype. Completely randomized design tests with fifteen replications were performed in laboratory. Larval weight at seven days, time to pupation, pupal weight and time to adult emergence was registered.

Antixenosis was evaluated in field conditions. Potted plants were included in 36 m² cages, where 50 mated females of either species were released for each test. Moths were allowed to oviposit overnight. Next day the number of eggs deposited on leaves, stem and bracts was registered. Tests were run during five different dates, each with 10 replications in a randomized complete block design.

Antibiosis tests showed significant differences ($P < 0.05$; $n = 3$) among genotypes. The lightest larvae were obtained from genotypes "Guazuncho 2 INTA" and "pool of advanced lines".

Significant differences ($P < 0.05$; $n = 5$) were also obtained among genotypes tested for antixenosis. The highest levels were observed in genotypes "without trichomes" and "okra leaf without trichomes".

22-131

HELIOTHIS VIRESCENS (F.) (LEPIDOPTERA: NOCTUIDAE): ANALYSIS OF MOVEMENT DATA AND ESTIMATION OF THE SCALE OF AREA-WIDE SUPPRESSION PROGRAMS

J. C. Schneider

Department of Entomology & Plant Pathology, Mississippi State University, Mississippi State, MS, USA

Suppression of *Heliothis virescens* (F.) over an area large enough to appreciably delay population increase due to immigration has been attempted by release of a sterile male-producing interspecific hybrid, destruction of wild host plants, and application of a nuclear polyhedrosis virus. The results from these tests have been equivocal: due, in large part, to inadequate size of the areas treated relative to typical distances moved by *H. virescens*.

Releases of up to 1,600,000 laboratory-reared males were made near Greenville, MS, USA during eclosion of overwintering populations in each of 1982, 1983, 1993, and 1994. Males were recaptured in up to 120 pheromone traps over an area of 4,000 km². Cumulative trap catch was fitted to a model that assumed a constant diffusion coefficient and rate of mortality. Estimates of median distance moved are 11, 8, 23, and 16 km, respectively.

In 1994, blanket treatment with nuclear polyhedrosis virus of an area 32 km in diameter near Greenville, MS, USA resulted in a 59% reduction in survival of the offspring of overwintering *H. virescens*. Movement into this area of suppression was simulated by a computer program that assumed movement of females is the same as that observed for males, movement is identical in different generations, and population growth rate is density independent. For a median distance moved of 16 km, suppression of the next larval generation was estimated to range from 35% to 18% at the middle and edge of the suppression area, respectively. The level of suppression in the following generation dropped to 23-15%. Given the sample sizes used, these levels of suppression were below statistically detectable levels; and, indeed, treatment effects were not significant.

22-132

LOW COST MEDIA OF THE MEDITERRANEAN FRUIT FLY, *CERATITIS CAPITATA* (WIED.) (DIPTERA: TEPHRITIDAE) FOR USE IN AN INTEGRATED MANAGEMENT SYSTEM

A.G. Manoukas, E.N. Zografou

Biology Institute, National Center for Scientific Research "Demokritos", Athens 153 10, Greece.

Low cost larval media were evaluated for rearing the genetic sexing strain GSWP-1-62 (white pupa) of the Mediterranean fruit fly, *Ceratitis capitata* (WIED.) (Diptera: Tephritidae), as part of a male sterile release program in an experimental citrus orchard in Greece. The media were made up of low cost and locally available ingredients.

The media proved to be equivalent or better when compared to a control which was routinely used for mass rearing of this insect. The best medium gave pupal number higher than the control and all other parameters recorded equivalent to the control. Thus number of pupae/g for this medium was 18.0 compared to 10.3 for the control, while hatchability of eggs, pupal weight and adult emergence was 82.7 %, 8.1 mg/pupa and 95.2 % for the experimental medium and 79.7 %, 8.5 mg/pupa and 94.3 % for the control, respectively. The effect of certain other ingredients was also evaluated.

22-134

ATTRACTIVE CAPACITY OF AGGREGATING PHEROMONE TO ADULTS OF THE COTTON BOLL WEEVIL, *Anthonomus grandis* BOHEMAN (COLEOPTERA, CURCULIONIDAE) DURING BETWEEN-SEASON PERIOD

W.D. FERNANDES*, S.L. CARVALHO** & M.E.M. HABIB***

* Dept. Biol. Sciences, Federal Univ. Mato Grosso do Sul, Dourados, MS, 79825-070., Brazil. ** Dept. Appl. Biol. For Agriculture, UNESP, Ilha Solteira, SP, 15378-000, Brazil. *** Dept. Zoology, Inst. Biology, State Univ. Campinas (UNICAMP), Campinas, SP, 13081-970, Brazil.

The cotton Boll Weevil, *Anthonomus grandis*, was detected in São Paulo State, Brazil, in 1983 (Habib, Fernandes, 1983) and now is considered as a key pest in cotton fields in this country. The present study was undertaken to investigate the attractiveness of boll weevil adults to its aggregating pheromone (grandlure) under winter field conditions.

At the end of the cotton season, adult populations disperse looking for alternative food and reproductive resources and refuges to spend the between-season period. Attraction and kill could be considered as a benefit strategy during such a period. Two experimental fields, at Casa Branca City, State of São Paulo, were utilized. For each one, three areas (300 m² each) were established near forests or orchard, with 500 m distance between them, to receive pheromone applications. Each area was divided in three sub-areas (100 m² each). The distance between the 1st. sub-area and the refuge was 20 m; while the distance between the 3 sub-areas was only 10 m. The pheromone capillaries were distributed homogeneously (2.5 g per m²). In addition to the pre-application counting, 5 evaluations were realized after treatment in each sub-area. 10 randomized samples (1m² each) was considered for each sub-area. Boll weevil adult response to pheromone was immediate, and prolonged up to 14 days. The highest level of attractiveness, however, was observed 24 hours after applications. Chemical control in small plots, can be recommended 24 hours after pheromone applications as a between season strategy for the control of *A. grandis* adults.

22-133

MEDITERRANEAN FRUIT FLY ERADICATED FROM CHILE: ONE MORE SUCCESSFUL APPLICATION OF THE STERILE INSECT TECHNIQUE

O. Morales¹, C. Lobos¹, G. Ortiz² and B. Radischat³

¹ Departamento de Protección Agrícola, Servicio Agrícola y Ganadero, Santiago, Chile -² Insect and Pest Control Section, Joint FAO/IAEA Division of Nuclear Techniques in Food and Agriculture, Vienna, Austria -³ Latin America Section, Technical Cooperation Department, IAEA Vienna, Austria.

A Sterile Insect Technique (SIT) Mediterranean fruit fly eradication project in Chile culminated in the eradication of this pest from the country, with benefits to the economy estimated at US\$ 500 million per year. In a ceremony presided over by the former President of Chile, the country was officially declared Mediterranean fruit fly-free on December 1995.

Although the southern and central regions of Chile were already free of fruit flies and the country had developed a very successful fruit export industry, its produce was still being restricted from certain international export markets because of fear of outbreaks originating from the presence of medfly in the Arica region in northern Chile. After a decade of unsuccessful attempts to eradicate the fly using insecticides in the Arica region, the Chilean Agricultural Service, with the technical and financial support from the IAEA, initiated a Sterile Insect Technique eradication programme against this pest. As a consequence, a medfly mass rearing facility with a production capacity of ca. 60 million sterile flies per week was completed in 1993, when sterile fly releases were initiated. No wild medflies have been detected in the Arica region since the first half of 1995. In addition, the pest has already been suppressed in Tacna, the southern-most valley of Peru.

Future collaboration within an expanded FAO/IAEA bi-national Chile-Peru project foresees enlarging the eradication and control activities to other fruit-producing valleys in southern Peru.

22-135

CONTROL OF *PECTINOPHORA GOSSYPIELLA* (SAUNDERS) (LEPIDOPTERA: GELECHIIDAE) USING TWO PHEROMONE MATING DISRUPTION METHODS

G. Videla¹, B. Frias², G. Diez Rodriguez¹, J. Soto²

¹ Departamento de Entomología, Instituto Nacional de Tecnología Agropecuaria, Sáenz Peña, Chaco, Argentina

² Departamento Técnico, Finca Tolloche, El Quebrachal, Salta, Argentina

Pink bollworm (pbw), *Pectinophora gossypiella* (Saunders) is a relatively serious pest of cotton toward the end of the season in Argentina. Chemical control is avoided due to insecticide resistance management program for other pests, such as Heliothinae. Therefore, emphasis is devoted to evaluate more specific type of controls. Pbw pheromone (Hexadecadienyl Acetate) is used throughout the cotton area of Argentina to bait monitoring traps only. Rings containing pbw pheromone (Selibate PBW-rings[®]) and sprayable pbw pheromone formulations (Check Mate[®] and No Mate[®]) were evaluated as mating disrupters during 1995 and 1996 (in progress).

Field tests were performed. Rings were evaluated in an 8 ha plot during 1995; the other two formulations were tested in large areas (more than 500 ha each), during 1995 and 1996. When significant differences ($P < 0.05$) in captured pbw moths were detected between treatments (with and without pheromone), higher numbers were found in control plots. No significant differences between treatments were detected for infestation of fruit forms. Seed index was significantly lower in pheromone treated plots. More lint resistance was observed, although not always significant, in plots with pheromone.

For the given experimental conditions, results are considered promising in favor of a reduction of the pest in pheromone treated plots. Practicality of both methods, and also 1996 results are discussed.

22-136

EFFICACY EVALUATION OF *BACILLUS THURINGIENSIS* AND NEEM SEED OIL, *AZADIRACTA INDICA* ON POTATO TUBER-MOTH IN THE FIELD AND DURING STORAGE

S.A. Salem, M.S. Foda

Department of Plant Protection and Microbial Chemistry, National Research Centre, Dokki, Cairo, Egypt

A new approach was used for evaluation of the efficacy of *Bacillus thuringiensis* and pure neem seed oil on the potato tuber-moth, *Phthorimaea operculella* in the field and store. Both the two materials were found equally effective on the potato tuber-moth infestation. The infestation percentage could be significantly reduced by frequent application of both in the field up to harvest and also during the storage. No clear synergistic effect could be observed upon application of the two preparations simultaneously. The results obtained suggest their possible use as substitutes for hazardous chemical insecticides in combating the pest both in the field and during storage.

22-137

INTEGRATING *BACILLUS THURINGIENSIS* INTO AN IPM PROGRAM IN CELERY

William G. Carson and John T. Trumble

Department of Entomology, University of California, Riverside, CA 92521 USA

Economic analyses were conducted on celery plantings in 1992 and 1993 at a field station which compared the benefit of current 'chemical standard' pesticide practices to an IPM program based on a registered *B. thuringiensis* preparation and an untreated control. The chemical standard treatment consisted of 9 applications of methomyl and permethrin. The IPM program used 3 or 4 applications of *B. thuringiensis* as needed. The impact of each pesticide use program on insect populations, fruit damage, yield, crop value, cost of control, and net profit was determined. Both the chemical standard and IPM treatments reduced pest populations and damage, resulting in better yield and net profits as compared to the control treatment. The reduced input costs of the IPM program resulted in better return in both years. In 1992, net profits were higher by about \$200/ha. In 1993, all treatments lost money, but the IPM program lost approximately \$60 less per ha than the chemical standard treatment. In 1995, a large scale, replicated trial was conducted with a commercial celery grower. The IPM program proved significantly more economical. Fewer applications of less toxic pesticides were required to produce an equivalent amount of product. The economic results from the IPM program were conservative as some substantial benefits were not included in the analyses. These include a reduction in development of pesticide resistance, reduced soil compaction, less potential for damage to the environment, and less possibility of human health concerns.

22-138

BIOLOGICAL AND INTEGRATED CONTROL PROGRAM AGAINST INSECT ATTACK ON BELL PEPPERS GROWN IN GREENHOUSE
E. Fiume, M. Milone, B. Parisi

Sezione di Biologia, Fisiologia e Difesa, Istituto Sperimentale per l'Orticoltura, Pontecagnano (SA) Italy

In order to develop a fruit growing greenhouse system with a minimum input of pesticide, five different sweet pepper growing systems were set up, compared and managed.

One system was a biological greenhouse system, the second system was an integrated one, the third system was an integrated system in which were used biopesticides (such as *Bacillus thuringiensis* Berliner sub sp. *kurstaki*) instead of chemicals, the fourth was a system where only chemicals were applied and the last one was an untreated one. The experimental design was a complete randomized block replicated four times. The target pests were *Frankliniella occidentalis* (Pergande) and *Ostrinia nubilalis* (Hb.). They were monitored by observing flowers and blue traps (thrips), by using pheromone traps (moths) and by evaluating the fruit damage (both). Yield and earliness were noticed.

The best control of *F. occidentalis* was obtained for the biological and integrated systems where *Orius laevigatus* (Fieber) was released four times from June 1st to July 6th, 1995. Less damage to fruits was observed for the same systems too. With regard to *O. nubilalis* control, the best results were registered only by the systems where integrated control was applied by using hexaflumuron or *B. thuringiensis* *kurstaki*.

The highest yield was obtained by the systems including integrated control and only chemical applications. The best earliness was performed by biological and untreated systems. Lack of chemicals induced the plants to earliness.

If invited speaker, indicate title of session and name(s) of organizer(s):

22-139

CONTROL OF *CACOPSYLLA PYRI* (L.) (HEMIPTERA: PSYLLIDAE) BY JUVENILE HORMONE ANALOGUES

N. Baldassari, P. Baronio, V. Nemeček, M. Rejzek, Z. Wimmer

Unità Complessa di Istituti "Scienze e Tecnologie Agroindustriali e Agroambientali", Università degli Studi di Bologna, Bologna, Italy - 1 Institute of Entomology, Czech Academy of Sciences, České Budějovice, Czech Republic - 2 Institute of Organic Chemistry and Biochemistry, Czech Academy of Sciences, Praha, Czech Republic

The commercial juvenoids, methoprene and hydroprene as well as twelve new juvenoids were tested on the populations of *Cacopsylla pyri* (L.) (Hemiptera: Psyllidae) and on the predatory bug, *Anthocoris nemoralis* (Fabricius) (Hemiptera: Anthocoridae) by the indirect contact application.

It was found that even low doses of the active juvenoids evoked in *C. pyri* the malformations of wings and external genitalia which disabled them from flying and copulation. The period of sensitivity to juvenoids comprised in *C. pyri* the first 4 days of the last instar nymphs, in *A. nemoralis* only the first 24 hr of the last instar nymphs. Sensitivity of *A. nemoralis* to the tested juvenoids is very low. Thus juvenoids could be a useful tool for the control of psyllids without endangering their natural regulators, the bugs family Anthocoridae.

22-140

APPLICATION AND IMPORTANCE OF INSECTPATHOGENIC VIRUSES IN RESPECT TO THE INTEGRATED PEST MANAGEMENT (IPM)

K. Geißler

Martin-Luther-Universität Halle-Wittenberg, Institut für Pflanzenzüchtung und Pflanzenschutz, Arbeitsgruppe Aschersleben, Germany

There is given a survey about possibilities of using insectpathogenic viruses as biological pesticides in frame of Integrated Pest Management Systems (IPM). Results of control experiments with insectpathogenic viruses against *Mamestra brassicae* L., *Agrotis segetum* SCHIFF. and *Cydia nigricana* Steph., respectively, under greenhouse and field conditions are interpreted. The merits and disadvantages of insectpathogenic viruses are discussed.

22-141

LONG TERM EFFECT OF INSECTICIDES UPON NATURAL ENEMIES OF SOYBEAN PESTS.

I. C. Corso, D. L. Gazzoni

National Soybean Research Center, Brazilian Agricultural Research Enterprise (CNPSo/EMBRAPA), Londrina-PR, Brazil

A field experiment was conducted at Sertãozinho county (Paraná-Brazil), during the 1993/94 soybean season, aiming to evaluate the impact of insecticides on predators and parasitoids of soybean pests, along all the soybean cycle. Experimental design used was random block, with three replications, and plots measuring 100x100 m. The treatments consisted of two insecticide applications (velvetbean caterpillar / stink bug control). Insecticides and rates used were: a. Endosulfan 210 g ia.ha⁻¹/endosulfan 525 g ia.ha⁻¹; b. lambda-cyhalothrin 4.5 g ia.ha⁻¹/lambda-cyhalothrin 9 g ia.ha⁻¹; c. monocrotophos 96 g ia.ha⁻¹/monocrotophos 180 g ia.ha⁻¹; d. *Baculovirus anticarsia* 24 g pc.ha⁻¹/monocrotophos 120 g ia.ha⁻¹ + NaCl 0,5%; and e.check. The shock method was used to evaluate the insect population, which consisted on the application of 2% of mevinphos, a potent and broad spectrum insecticide, collecting the dead insects fell on a ground cloth after 15 minutes. The insects collected on the samples were identified and counted on the laboratory. Statistical analysis indicated that lambda-cyhalothrin was initially more toxic to predators, and that none of the treatments affected the parasitoids species present on the field, or the parasitism index on caterpillars or on stink bug eggs. Larval mortality by entomopathogenous was larger on plots where insecticides were applied, probably due to sub-lethal intake rates, which stressed the surviving larvae, and depressed its enzymatic detoxification system.

22-142

SELECTIVITY OF INSECTICIDES UPON NATURAL ENEMIES OF SOYBEAN PESTS, EVALUATED SEASON-LONG.

I. C. Corso, D. L. Gazzoni

National Soybean Research Center, Brazilian Agricultural Research Enterprise (CNPSo/EMBRAPA), Londrina-PR, Brazil.

During the 1994/95 soybean season, a field trial was conducted at Sertãozinho county (Paraná-Brazil), aiming to evaluate the impact of insecticides on predators and parasitoids of soybean pests, along all the soybean cycle. Experimental design used was random block, with three replications, and plots measuring 100x100 m. The treatments consisted of two insecticide applications (velvetbean caterpillar / stink bug control). Insecticides and rates used were: a. Endosulfan 175 g ia.ha⁻¹/endosulfan 437.5 g ia.ha⁻¹; b. lambda-cyhalothrin 3.75 g ia.ha⁻¹/lambda-cyhalothrin 7.5 g ia.ha⁻¹; c. monocrotophos 80 g ia.ha⁻¹/monocrotophos 150 g ia.ha⁻¹; d. *Baculovirus anticarsia* 24 g pc.ha⁻¹/monocrotophos 100 g ia.ha⁻¹ + NaCl 0,5%; and e.check. The shock method was used to evaluate the insect population, which consisted on the application of 2% of mevinphos, a potent and broad spectrum insecticide, collecting the dead insects fell on a ground cloth after 15 minutes. The insects collected on the samples were identified and counted on the laboratory. Statistical analysis did not indicate differences among the treatments on any of the sampling dates, considering the predators or parasitoids population, or the parasitism indexes. Although not statistically different, the lower predators population was found on treatments of endosulfan, lambda-cyhalothrin and monocrotophos, when applied twice, for the control of velvetbean caterpillar and stink bugs.

22-143

PETROLEUM SPRAY OIL: SPRAY VOLUME, OIL CONCENTRATION AND INSECTICIDAL ACTIVITY

G.A.C. Beattie and G.A. Herron

NSW Agriculture, Biological and Chemical Research Institute, Rydalmere, NSW, Australia.

Since the development of low-volume and ultra-low-volume sprayers in the 1970s there has been a tendency to introduce this technology into horticultural crops. Its main advantages are reduced machinery and labour costs, and less wastage of active ingredient. This is achieved by optimising coverage using ≤ 200 μ m droplets.

In field and laboratory studies we have demonstrated that low-volume spraying is not appropriate for the application of petroleum spray oils (PSOs). When oil deposit is held constant there is a significant increase in PSO efficacy as spray volume is increased. PSOs require minimum amounts of diluent to be effective. We suggest that thorough wetting of sprayed surfaces and droplet coalescence are required for their effective use. For PSOs, run-off should not be considered waste.

22-144

INTEGRATED PEST MANAGEMENT OF EGGPLANT ARTHROPODS WITH SELECTIVE PESTICIDES: A PLAN TO CONTROL SPIDER MITES, *Tetranychus* spp., RESURGENCE.

H. Nemoto

Saitama Horticultural Experiment Station, Kuki, Saitama, Japan.

Eggplant in experimental plot were continuously sprayed with the insecticide permethrin, milbemectin, and fenbutatin oxide to evaluate their respective side-effects. Effect of population of pests and of their natural enemies were assessed. The result revealed the importance of natural enemies such a anthocorid bugs, *Orius* spp. Application of permethrin may cause resurgence of *Aphis gossypii* and *Thrips palmi* population because of (1) the development of resistance by the pests and (2) nonselective killing of the predators.

The author therefor attempted to develop methods of control of pests that would not affect substantially natural enemies. Respective treatment with granules of Asetamiprid, Nitenpyram and Imidacloprid at the time of planting enabled to control *A. gossypii* and *T. palmi*. But these pesticides caused resurgence of *Tetranychus* spp.

Milbemectin and fenbutatin oxide which exerts minimaized adverse effect on *Orius* spp. when used in combination with the granule of Imidacloprid, Asetamiprid or Nitenpyram, maximized these granule's advantage while minimizing those disadvantages.

22-146

KNOWLEDGE-BASED DECISION SUPPORT SYSTEM FOR MANAGEMENT OF WESTERN AND NORTHERN CORN ROOTWORM (COLEOPTERA: CHRYSOMELIDAE)

W. D. Woodson, M. M. Ellsbury, L. D. Chandler
Northern Grain Insects Research Laboratory, Agricultural Research Service, United States Department of Agriculture, Brookings, South Dakota, USA

Research on the biology, ecology, and management of the western and northern corn rootworm complex has and is continuing to generate knowledge useful for pest management decision making. A knowledge based decision support system is presented for the management of western and northern corn rootworms. The system consists of simulation models of rootworm phenology, corn phenology, and an expert system to assist in pest identification, record keeping, and pest management decision making. Spring treatment decisions are determined by previous adult counts and estimates of over winter egg survival, enabling producers to determine the potential for damage at planting. Late summer treatment decisions are determined by adult counts and predictions of adult emergence. Ancillary components include a record keeping system for weather data, pesticide usage, and scouting reports. Working together, these components assist producers in properly parameterizing component models, entering current and past weather information, and performing what-if scenarios related to their production practices.

22-145

FORECASTING PROTECTION OF VINEYARDS FROM LOBESIA BOTRANA SCHIFF. (LEPIDOPTERA: TORTRICIDAE)

Abashidze E.

Department of Forecasting, Plant Protection Institute, Tbilisi, Republic of Georgia

The intensive use of pesticides for vineyard protection from the grapevine moth - *Lobesia botrana* have led to environment pollution, decrease of biodiversity, appearance of resistance population of noxious organisms. Applying in vineyard against grapevine moth phosphororganic pesticides promoted the reproduction of *Shyzo-tetranychus pruni* on the large scale, decrease of predatory mites and other beneficial organisms.

In the result of research the forecasting protection of vineyards from grapevine moth based on reliable prognosis of phenology and dynamic population of *Lobesia botrana* was worked out. This method has made possible to decrease pesticide press and conservation of the beneficial fauna.

22-147

THE UTILIZATION OF INSECT-PROOF NETS IN ISRAEL'S AGRICULTURE

D. Hadar¹ and D. Nestel²

Klayman-Meteor, 21 Hayetzira St., Petah-Tikva 49130, Israel-1
Department of Entomology, Institute of Plant Protection, Agricultural Research Organization, Bet-Dagan 50250, Israel-2

During the last years, we have been using insect-proof nets in different agricultural systems as a strategy of pest control. Good pest control has been obtained in vegetables (specifically in tomato), Herbs and flower greenhouses, and in fruit orchards (dates, figs, pomegranate apple, mango, peach and grapes). Results from several experiments in all these crops, and from commercial agroecosystem that already established the use of nets as a standard agronomical practice (e.g. tomato), show that the main complex of insect pests, and insect vectors, attacking these crops is significantly reduced, or eliminated. Moreover, our experience shows that insect-proof nets highly improved the quality of the crop by its direct action on the reduction of insect pests, and by reducing the negative effect of other environmental factors (such as extra sun radiation, highstorm, frost, etc.).

22-148

THE DENSITY OF GROUND DWELLING ARTHROPODS IN IPM AND CONVENTIONAL APPLE ORCHARDS IN HUNGARY

V. Markó¹, I. Rácz², K. Spilák¹, S. Bogya¹, K. Balázs³

- 1 University of Horticulture and Food Industry, Department of Entomology, Budapest, Hungary - 2 Kossuth Lajos University, Department of Zoology, Debrecen - 3 Plant Protection Institute of Hungarian Academy of Sciences, Budapest

Ground dwelling arthropod assemblages were studied in integrated /IPM/ and conventional /CON/ apple orchards by pitfall trapping in 1992 - 1994 in Hungary.

- The density of *Heteroptera* and *Coleoptera* /both predator and phytophagous/ assemblages were higher in IPM blocks.
- The densities of *Dermaptera* were higher in the IPM blocks in 1992 - 1993, on the other hand, they were more abundant in the CON block in 1994.
- The spider assemblages were not different in size /IPM-CON/ in 1992 - 1993, but in 1994 the number of individuals was higher in IPM blocks.
- The size of the *Orthoptera* assemblages were higher in IPM blocks only in the year of the outbreak, in 1993.

22-150

DAMAGES OF *PLUTELLA XYLOSTELLA* (L.) (LEPIDOPTERA-PLUTELLIDAE) ON BROCCOLI IN APULIA AND POSSIBILITY OF INTEGRATED PEST MANAGEMENT.

F. Baldacchino, T. Moleas

Istituto di Entomologia agraria,
University of Bari, Italy

Some years *Plutella xylostella* (L.) (Lepidoptera Plutellidae) proves to be one of the most harmful pests of broccoli (*Brassica oleracea botrytis* L.) in Apulia (South Italy). This is one of the autumn-winter vegetables among the most exported to Northern Europe where markets require pesticide residues-free products. Therefore it was necessary to evaluate the pest damages in the Mediterranean environment to find some parameters hampering its pullulations thereby reducing or eliminating the use of pesticides.

This work was carried out in 1994-95 in plantings located in Cerignola area (Foggia). Over these two years the following results were obtained : a) the actual damages caused by *P. xylostella* in nursery beds where a very high infestation percentage was observed (100%) during the peak population period; b) after transplanting, a reduction of damages induced by the lower infestation percentage on more developed plants; c) the impact of climatic factors showing that plants can escape the pest damages by postponing the growing season; d) the presence of some parasitoids.

22-149

EFFECT OF LEVEL OF DEFOLIATION ON RECOVERY OF LEAF AREA AND ON YIELD AND AGRONOMIC TRAITS OF SOYBEAN *Glycine max* (L.) Merrill

D. L. Gazzoni, F. Moscardi

National Soybean Research Center, Brazilian Agricultural Research Enterprise (CNPSo/EMBRAPA), Londrina-PR, Brazil

Four levels of defoliation (0, 33, 67 and 100%) were applied at four stages of development (V_3 , V_8 , R_2 and R_6) of soybeans - cv. Paraná, at EMBRAPA/CNPSo experimental station (Londrina-PR, Brazil). Defoliation was made by hand, cutting one leaflet of each leaf for each 33% of defoliation. Recovery of leaf area was measured at five and 12 days after defoliation, and mathematical simulations were made to study parameters of recovery. Results indicated intense recovery measured by liquid daily rate of leaf area increase (dr) and recovery time (rt) for low defoliation levels, specially when applied at vegetative stages. During the reproductive period, levels of defoliation reduced the rate of the soybean natural trend of losing leaf area. Yield was affected only by 67 and 100% defoliation applied at R_6 , while main agronomic traits such as date of harvesting maturity, plant lodging and plant height were not affected by the treatments.

22-151

COMPARISON OF SOYBEAN INSECTS SAMPLING METHODS. II. PREDATORS, DIPTERA AND HYMENOPTERA.

D. L. Gazzoni, I. C. Corso, P. C. Francovig

1 National Soybean Research Center, Brazilian Agricultural Research Enterprise (CNPSo/EMBRAPA) - 2 - State University of Londrina, Londrina-PR, Brazil.

The shock technique is a variant of the beat cloth method of sampling soybean insects, developed to overcome the disadvantage of the original method, of heavily underestimating population of flying adults of several orders, specially Diptera and Hymenoptera. To compare the results of the two sampling methods, four experiments were set up during 1992/93 soybean season and one during 1994 season, while during 1995 both methods were compared to the sweep net. All experiments were set up in the Londrina region (Paraná-Brazil). Results indicated that beat cloth and shock methods are similar when sampling predatory arthropods, but the shock method proved to be more efficient when sampling species of Diptera and Hymenoptera. Based on these results, the shock method is recommended when sampling these insect orders, specially when involving biological control evaluations, or insecticide selectivity to predators and parasitoids.

VECTOBAC 12AS, AN ENVIRONMENTALLY FRIENDLY MOSQUITO CONTROL SUBSTANCE

T.C. van der Linde

Dept. of Zoology & Entomology, University of the Orange Free State, Bloemfontein 9300, South Africa

In view of the importance of sheep farming in South Africa and the incidence of stock diseases related to increased mosquito numbers during years of high rainfall together with the fact that various mosquito species can act as vectors of various human diseases it is important to find an effective, environmentally friendly and economically affordable control method for mosquitoes.

In evaluating VectoBac 12AS, laboratory and field surveys were done using various concentrations of VectoBac 12AS. Laboratory reared larvae of *Aedes aegypti*, *Eretmapodites quinquevittatus*, *Culex theileri*, *Cx. quinquefasciatus*, *Culiseta longiareolata* and field collected *Anopheles squamosus*, *An. cinereus*, *An. coustani* and *Cx. theileri* were used in the laboratory trials. After treatment with 0,05 ml VectoBac 12AS/m², 100% mortality occurred within 12 hours. However, 1,3% of *Er. quinquevittatus* and 16,7% of *An. cinereus/coustani* survived for 5 days after exposure to 0,25 ml VectoBac 12AS/m².

Under field conditions *Cx. theileri*, *Cs. longiareolata* and *An. squamosus* showed up to 80% mortality within 24 hours after treatment with 0,5 ml VectoBac 12AS/10 m². After treating with 2,5 ml VectoBac 12AS/10 m² more than 85% of the larvae died. The pupal stage was not affected by VectoBac 12AS.

Natural occurring non-target organisms e.g. Ephemeroptera larvae, Odonata larvae (Anisoptera & Zygoptera), Hemiptera adults and larvae (Notonectidae & Geridae), Coleoptera larvae (Dytiscidae), Copepoda and Amphibia (*Xenopus laevis*) were exposed to VectoBac 12AS at doses up to 5 ml VectoBac 12AS/m². No treatment related mortalities occurred. However, chironomid larvae (Diptera) were affected by VectoBac 12AS. At a dosage of 0,5 ml VectoBac 12AS/10 m² a mortality of more than 90% occurred.

From the results obtained it is concluded that VectoBac 12AS is a very effective substance to control mosquito larvae. At a cost of approx. US \$5 to treat one hectare of water, VectoBac 12AS is also an economically affordable product for mosquito control.

23-001

ACYLATED 1,3-AMINOPROPANOLE DERIVATIVES AS REPELLENTS AGAINST BLOOD SUCKING ARTHROPODS - STRUCTURE/ACTIVITY-RELATIONSHIPS AND EFFICACY IN THE FIELD

G. Nentwig, F.P. Hoefer, B.W. Krüger, K. Röder

Bayer AG, D-51368 Leverkusen

m-Diethyltoluamide (Deet), an effective repellent against blood-sucking Diptera, has been used widely throughout the world for the last 40 years.

However, this compound is irritating to mucosa and aggressive towards some plastic materials. Our aim was to find new compounds with at least the same efficacy as Deet but without these disadvantages.

The chemical synthesis of the title compounds, which split into several groups with high biological activity, and molecular modelling aspects are described.

The substances were screened for repellent activity against *Aedes aegypti* on guinea pigs, and those giving a longer protection period than Deet were further tested against *Anopheles stephensi*, *Culex quinquefasciatus* and *Stomoxys calcitrans*.

Structure/activity relationships on *Aedes aegypti* revealed hydroxypiperidines acylated at the nitrogen and with a special spatial relationship of the two oxygens as well as a lipophilic side chain attached to the carbonyl group to be the most effective compounds.

The best substance (1-Piperidinecarboxylic acid, 2-(2-hydroxyethyl)-, 1-methylpropyl-ester, lab code KBR 3023) in laboratory tests on guinea pigs proved superior to Deet against all insect species tested and also with respect to irritation of mucosa and neutrality towards plastics.

In field trials this compound was demonstrated to be equal or superior to Deet against many dipteran insects and ticks.

23-003

BEHAVIOUR OF THE HORN FLY AND ALTERNATIVE CONTROL STRATEGIES

J.B. Jespersen and K.M.V. Jensen

The Danish Pest Infestation Laboratory, Ministry of Agriculture and Fisheries, Lyngby, Denmark

Traditionally the horn fly *Haematobia irritans* (L.) is controlled by using insecticides. However, due to e.g. insecticide resistance problems, concern for the environment, and the use of organic farming methods there is an increasing need for alternative methods for control of this and other cattle-visiting fly species.

For this reason the behaviour of the horn fly has been studied, in particular the individual variation between cattle in resistance to horn flies, constancy of fly distribution over time and dispersal of hornflies within a herd. Data was produced by 2 to 4 daily observations of hornflies on individual heifers in two herds of cattle. The observations were made during August in two consecutive years. Flies were counted in five different areas of the heifers' body - head, back, side, belly and legs. For the dispersal studies horn flies were caught from one of the most fly susceptible cattle, marked with a fluorescent colour and then released onto the same heifer again. The dispersal of the marked flies within the herd was then followed for up to 24 hours.

Based on produced data trials were made to estimate the potential of manipulating horn fly behaviour. In this experiment the most horn fly susceptible cattle in one herd were interchanged with the most horn fly resistant cattle in a second herd. The fly-load per cattle and per herd was studied before and after the replacement. It was shown by the investigation, that it is possible to manipulate the fly-load per herd by changing the composition of fly-susceptible and fly-resistant cattle within the herd.

23-004

THE USE OF CHEMICAL AND VISUAL ATTRACTANTS TO OPTIMISE THE EFFICIENCY OF A CONTROL SYSTEM FOR THE HOUSE FLY, *MUSCA DOMESTICA* (DIPTERA: MUSCIDAE), IN POULTRY UNITS IN SOUTHERN ENGLAND.

J. W. Chapman

School of Biological Sciences, University of Southampton, Southampton, UK.

The house fly, *Musca domestica*, is an important pest in poultry units, where its presence in large numbers can constitute a considerable nuisance and public health problem. The traditional control technique used in intensive animal rearing units is the application of residual insecticides. Continued use of toxicants has resulted in high levels of resistance developing to all the major groups of contact insecticide employed. This problem has become particularly acute in southern England, where many poultry farms have become populated with multi-resistant strains of *M. domestica*. For these reasons attention has recently switched to control methods that minimise the use of insecticides.

One such method is to present the insecticide in localised toxic baits, where the mode of action is through ingestion of the toxin. This results in a reduced level of insecticide released into the environment, and lower selection pressure for resistance to appear. However, for toxic baits to form an efficient component of a control strategy they must attract *M. domestica* in sufficiently large numbers.

M. domestica sex pheromone, (Z)-9-tricosene, is known to have potential for increasing the attractiveness of toxic baits. Field trials have therefore been conducted to investigate the effects of providing visual cues, sex pheromone and food odours on the attractiveness of toxic bait traps. The results of these trials, and their implications for house fly control, will be discussed.

23-006

QUALITY OF FILTH FLY PARASITES RELATIVE TO EFFECTIVENESS

G. L. Greene and Y. J. Guo

Agricultural Experiment Station, Kansas State University, Garden City, KS USA 67846

Pteromalidae have been sold for filth fly control in the US with numerous user questions and complaints relative to their effectiveness. During 1982 we began monitoring the species, emergence % and numbers released in confined cattle facilities. The species was different than claimed, emergence was low and variable, and the number delivered was much less than needed. To correct these problems we sampled feedlots, determined the natural parasite complex present, then developed rearing methods to produce the dominant pteromalid species attacking the stable fly, *Stomoxys calcitrans* (L.).

Mass releases of *Spalangia nigroaenea* Curtis in an IPM system have been successful in reducing stable flies below economic damage levels. This species has been the primary parasite of stable flies, even when other species were being mass released. It appears to be better adapted for searching and finding stable fly pupae for oviposition. *Muscidifurax* spp. have been recovered from house fly, *Musca domestica* L., pupae (90% of the sampled *Muscidifurax*) with very low numbers from stable fly pupae. Release of *Muscidifurax* spp. has been less successful for house fly or stable fly reduction.

23-005

AUTOSTERILIZATION OF THE HOUSE FLY, *MUSCA DOMESTICA* (DIPTERA: MUSCIDAE) IN POULTRY HOUSES IN NORTH EAST INDIA.

J.J. Howard

School of Biological Sciences, University of Southampton, Bassett Crescent East, Southampton, U.K.

Autosterilizing devices attract and sterilize wild flies in the field either directly, using chemosterilants, or indirectly, through transovarial disruption of the development of eggs, larvae or pupae. Some of the earliest autosterilizing systems developed for control of the cosmopolitan pest *Musca domestica* (Diptera: Muscidae) used alkylating agents such as tepa, metepa and apholate as chemosterilants. However, alkylating agents have never become widely used due to their high toxicity and minimal insect specificity, resulting in difficulties with safe deployment in the field.

More recently, a number of insect growth regulators (IGRs) have shown considerable potential as alternatives to the alkylating agents for use in autosterilizing systems. For the house fly, the chitin synthesis inhibitor, triflumuron has been shown to prevent egg hatch and larval development. Furthermore, exposure of female *M. domestica* to triflumuron on sucrose-baited targets in the laboratory induces significant transovarial ovidical and larvicidal effects and, following similar exposure, males are also capable of impairing the reproductive performance of unexposed females.

Field trials were therefore been carried out to evaluate the use of triflumuron treated, sugar-baited targets for autosterilization of *M. domestica* in poultry houses. The results of this fieldwork will be discussed in relation to the practical application of this technique for house fly control in livestock systems.

23-007

INTEGRATED PEST MANAGEMENT OF *DERMATOBIA HOMINIS* LIN. JR., 1781 (DIPTERA: CUTEREBRIDAE) IN LATIN AMERICA

G.E. Moya-Borja

Universidade Federal Rural do Rio de Janeiro, International Center for Tropical Myiasis, Rio de Janeiro, Brazil

Dermatobia hominis is one of the most important ectoparasites attacking cattle in Latin America. Studies on biology, ecology and chemical control of this insect have been carried out in our university. Based on these data we can suggest the following elements to be integrated for controlling *Dermatobia*:

1. When substantial larvae populations are present in cattle, insecticides treatments are the only recourse. The most appropriate insecticides are organophosphates, ivermectins, closantel or fenil-pirazol.
2. Keep clean the pasture lands to avoid the presence of micro habitats formed by bushes and weeds, which protect *Dermatobia* adults and their vectors.
3. Install traps to capture dipteran vectors, which carry *Dermatobia* eggs.
4. Reduce larvae of dipteran vectors of *Dermatobia* eggs associated with feces, treating cattle with IGR boluses.
5. Chemical control of ticks using new pyrethroids must be recommended, because these substances show good repellent effect on dipteran vectors and kill first instar larvae of *Dermatobia*.
6. *Dermatobia* resistant cattle like light color Zebu, should be recommended for highly infested regions, because dark colour animals are more attractive to the vectors of *Dermatobia* eggs.

23-008

WHERE DOES *ANOPHELES ARABIENSIS* BITE?

L. Braack, A. Gericke¹

Scientific Services, Skukuza, Kruger National Park, South Africa

¹ Department of National Health, Tzaneen, South Africa

Anopheles arabiensis Patton is the most important vector of malaria in southern Africa, yet little is known of its biting behaviour. A seasonally-abundant population of these mosquitoes at an isolated freshwater spring in north-eastern South Africa has allowed unique study opportunities.

More than 90% of *An. arabiensis* bites occur within 15cm off the ground. This means that in normal standing or seated position most bites occur on the feet and ankles. Our studies have also shown that covering the feet and ankles greatly reduces the number of bites. If prevented from feeding on ankles and feet, equivalent numbers of *An. arabiensis* do not move up to bite higher on the legs, but rather seek feeding opportunities elsewhere.

Exposure to *An. arabiensis* can be significantly reduced by covering feet and ankles, and by constructing residential units on stilts in areas having high risk of malarial infection by these mosquitoes.

23-010

FLYING UPWIND TOWARD ODOR PLUMES

R.T. Cardé

Department of Entomology, University of California, Riverside CA USA

Flying upwind to the source of an odor presents the challenge of continued detection of the wind's direction. An upwind course is set by optomotor anemotaxis, that is using a visual appraisal of how wind modifies the insect's path. A front-to-rear flow directly below an organism occurs when progress is due upwind. Details of this process have emerged mainly from wind tunnels studies of male moth flight to pheromone. In the field, changes in wind direction often cause a moth to lose contact with the scent, triggering casting, or a series of widening zigzags without upwind displacement. Continued contact with the odor plume yields upwind progress, usually in the form of zigzagging, a temporally regular pattern of counterturns across the windline. In moths, the precise course appears governed by moment-to-moment contact with odor. A brief contact with a pheromone filament causes a surge toward upwind, and an optimal rate of encountering filaments yields a course nearly straight upwind. Other insects such as parasitoid wasps 'seeking' a host do not seem to have such counterturning programs and often fly straight upwind. The success of these maneuvers in odor location is influenced by the pattern of odour dispersion, wind variability, and the availability of visual cues.

23-009

WIDESPREAD DISTRIBUTION OF INSECTICIDE IMPREGNATED CURTAINS ENTAILS A DRAMATIC REDUCTION OF MALARIA TRANSMISSION IN A HYPERENDEMIC AREA OF BURKINA FASO*

A. Habluetzel^{1&2}, A. van den Broeck², E. Sanogo², N. Cuzin², G. Diallo², S. Cousens³, A. Diabate², I. Nebic², L. Lamizana², F. Esposito^{1&2}

¹ Dipartimento di Biologia molecolare, cellulare e animale, Università di Camerino, Camerino, Italy - ² Centre National de Lutte contre le Paludisme, Ouagadougou, Burkina Faso - ³ London School of Hygiene and Tropical Medicine, London, UK

In a large scale trial involving 158 villages (c. 100000 population) in a rural area of Burkina Faso, insecticide impregnated curtains were installed in randomly selected clusters of villages. Each cluster included about 10 villages and covered an area of about 55 km². In two sentinel villages located in clusters receiving the intervention, the number of *Plasmodium falciparum*-infected *Anopheles* bites during the period from August to December was reduced from 444 to 32 and from 1252 to 36 following the intervention. After curtain installation, the circulating *Anopheles* populations decreased by more than 50% and sporozoite rates fell from 9.1% to 2.7% and from 13.2% to 5.7%. Similar falls were not observed in 2 control villages. We estimate that the individual protection against biting afforded by the curtains was of the order of 50% and 90%, and that the impact of the control measure on the vectorial capacity resulted in an overall protection against infected bites of 93% and 97%. These results indicate that, at least in areas of high transmission, a high level of coverage over a wide area may provide substantially greater protection against malaria transmission than the individual protection can offer alone.

23-011

THE EFFECTS OF PLUME FINE-SCALE STRUCTURE UPON PHEROMONE-MEDIATED FLIGHT BEHAVIORS OF MALE MOTHS

N.J. Vickers¹, T.C. Baker²

ARL, Division of Neurobiology, University of Arizona, Tucson, AZ USA - ¹ Department of Entomology, Iowa State University, Ames, IA USA - ²

Manipulations of the gross structure of pheromone plumes have long been used as an approach to understanding the behavioral mechanisms used by male moths to locate a calling female. Recently, experiments varying features of the temporal fine-scale structure of pheromone plumes have proved to be valuable in further dissecting those behavioral mechanisms. Two, independent studies have shown, in different species, that male moths are capable of responding to small wisps of pheromone (known as filaments) by making an upwind surge followed by a return to crosswind, casting flight. In multiple pulse plumes, generated at a threshold frequency, upwind progression by the Noctuid moth *Heliothis virescens* (F.) appears to be constituted by many such upwind surges with casting appearing as a function of the clean air gaps between filaments and the male's behavioral latency. Furthermore, in this same species of moth, filaments tainted by the presence of a novel inhibitor produced surges that are diminished compared to those occurring in response to normal blend filaments, providing a possible explanation for the reduced levels of upwind flight and source location that occurred in similarly tainted point-source plumes, where males would contact many such contaminated filaments per second.

Stationary electroantennogram (EAG) preparations have been used to determine how plume fine-scale structure can vary in differing physical conditions. In addition, we investigated the magnitude and frequency of pheromone filaments that a male moth might encounter during upwind flight in a plume by using an EAG attached to a flying male. Simultaneous video-recording of the olfactory response of the transported antenna and the male's flight path facilitated a correlation between olfactory input and behavioral output.

Our behavioral experiments underscore that the upwind flight performance of a male moth is strongly influenced by changes in both the temporal structure of a plume and the quality of moment-to-moment olfactory contacts.

Current neurophysiological investigations are aimed at understanding how central olfactory pathways in male *H. virescens* respond to changes in the temporal structure and olfactory quality of pheromone plumes.

DISPERSION OF HOST ODOUR PLUMES: MICROMETEOROLOGICAL STUDIES IN NATURAL HABITATS OF TSETSE FLY

F.X. Meixner, Ch. Ammann

Max-Planck-Institute for Chemistry, Biogeochemistry Department, Mainz, Germany

Tsetse fly in its natural habitat (African bush) uses carbon dioxide and some other gaseous constituents in plumes of host odour as chemical stimulus to find its host. There is laboratory evidence, that tsetse may not only react to step-wise increase of CO₂ concentration (over CO₂ background), but also to the (turbulent) fluctuations in the received 'CO₂-signal'. Besides the chemical stimulus, the odour plume provides also directional stimulus due its three-dimensional (turbulent) structure. Since surface layer turbulence determines (in-canopy) dispersion, it should also influence host finding of tsetse. At Rekomitjie Research Station (Zimbabwe) the dispersion and structure of CO₂-plumes was investigated by sensitive and fast response (<0.1s) measurements of CO₂ concentration and extended micrometeorological measurements (turbulent fluxes, vertical profiles of air temperature, wind speed and -direction) at several positions downwind a CO₂-source. During daytime the background noise of CO₂ was surprisingly low (< ±0.5 ppmv/5 min), which generally favours the detection of host CO₂ at considerable distances from the host. Detectable CO₂-signals were found even at >60m from the CO₂-source. Micrometeorological measurements of vertical temperature gradients have demonstrated the strong influence of surface layer stability on plume dispersion within the canopy. During unstable conditions (late morning to early afternoon) any released material was dispersed rapidly by thermal buoyancy forces to background concentration levels. However, the distant detection of host odour was mostly favoured under stable and neutral conditions (early morning and late afternoon), when the same material was kept very close to the surface during its turbulent transport through the bush.

THE SPEED AND EFFICIENCY OF ODOUR SOURCE LOCATION BY TSETSE FLIES (*GLOSSINA PALLIDIPES*); A MARK-RELEASE VIDEO STUDYN. Griffiths, J. Brady, Q. Paynter²Dept of Biology, Imperial College, Silwood Park, Ascot, Berkshire, UK
2. CABI/CSIRO, Unit of Biological Control, Montpellier, France

Individually marked tsetse flies (*Glossina pallidipes*) were released under video observation, in medium density bush, from 30-75 m downwind of an odour source and recaptured at the source by an electric net. In the absence of odour the proportion recaptured was <2% (approximately equal to random expectation from radial dispersal). When synthetic ox odour was emitted the proportion recaptured increased with proximity of release from 6% at 75m to 21% at 30m (though supplementary work implied around twice this number of flies entered the clearing by the odour source). The probability of recapture decreased with increasing wind speed but increased with the directness of the wind prior to take-off.

A clear distinction could be made between the release-recapture times of flies recaptured with odour. A 'fast' cohort of flies (approximately 50 % of recaptures) arrived within 40 s, with times normally distributed around a mean which increased linearly with release distance giving a mean rate of (straight line) upwind displacement of 2.8 ms⁻¹. The other 50% of recaptured flies were 'slow' - between 1 and >20 min. with a constant probability of arrival through time. No wind or temperature correlates with in-flight time were found although the probability that a fly was 'fast', decreased with increasing 'in-flight' wind speed.

The random nature of the 'slow' arrivals through time, presumably having lost the plume at some stage and/or rested on the way prevents any further inference of how they located the source. However the displacement rates of 'fast' flies together with the low probability of recapture with no odour imply they must have reached the odour source in a single uninterrupted flight step contacting the odour at some point from take-off to recapture. We infer that a form of biased random walk has been used to bring the insect within sight of the source, incorporating a combination of anemotactic 'aim-then-shoot' orientation from take-off plus optomotor-steered in-flight correction of direction.

23-013

EFFECTS OF WIND SPEED ON THE OLFACTORY FINDING OF HOSTS BY TSETSE FLIES (*GLOSSINA*)

John Brady and Nigel Griffiths

Department of Biology, Imperial College, Silwood Park, Ascot, United Kingdom

Wind speed in thick vegetation is slow (0-1 m/s). In such situations, it is highly non-linear (typically changing direction by > 10 °/s). As it increases speed (up to 1 m/s), however, its flow straightens out. When the wind in vegetation increases, therefore, odour plumes should be straighter, and hence be easier for insects to follow upwind to the source of the odour (whether mate or host).

This suggests that host-seeking insects such as tsetse flies should find it easier to locate hosts by odour in the faster winds of their bush habitat (i.e. in winds approaching 1 m/s (= ± straight)) than in the more typical weaker winds of their habitat (of around 0.3 m/s (= meandering)). This prediction was tested in the field in Africa several times, by means based on correlating the rate of arrival of tsetse flies at an odour source with the concurrent wind speed measured in various ways.

The real situation was more complicated: the relationship between source finding success and wind speed appeared to be bell-shaped. In some situations, arrival rate and wind speed correlated significantly positively (supporting the prediction), though always with low coefficients ($r^2 < 20\%$). In other situations, the same correlations were significantly negative (refuting the prediction).

Overall, the conclusion drawn is that - for tsetse flies at least - as the wind increases from near zero towards ca 0.5 m/s, flies do indeed find an odour source more easily. But as the wind increases to speeds above ca 0.7 m/s, the flies find it harder to locate odour sources, presumably because of the odour plume's greater dilution and fragmentation in the faster, more turbulent winds.

23-015

THE DYNAMICS OF AN ISLAND POPULATION OF TSETSE FLIES (*GLOSSINA* SPP.) IN ZIMBABWE

J.W. Hargrove

ODA/IPMI Tsetse Research Project, Harare, Zimbabwe

A mark-recapture exercise, carried out on Antelope Island between October 1979 and December 1983, provides a unique series of more than 200 consecutive weekly estimates of births and deaths, marked and total populations, and probabilities of capture and recapture for male and female *G. m. morsitans* Westwood and *G. pallidipes* Austen. Two approaches have been taken to the further analysis of the data. First, multiple regression has been used to produce a function which predicts the survival probabilities of adult and immature tsetse in terms of the known conditions on the island. (Maximum temperature and trapping intensity were shown to be the major determinants). Secondly, a new approach to the modelling of population data has been developed. The entire history of growth and decline was modelled using a stochastic process, starting from the pupae originally introduced onto the island. The life of each pupa was simulated using a Monte Carlo procedure. For both sexes the procedure made a daily test of survival; for females it also tested for the production of new pupae - whose life histories were, in turn, simulated. By including the birth process it was possible to model the male and female populations simultaneously. The survival function referred to above was used as a starting value for the procedure. The innovation comes in the linking of this procedure with a non-linear programme, whereby the parameters of the survival function can be optimised iteratively via a least squares fit to the whole series of (male and female) population estimates. By including the capture probability in the simulation process it is possible to model changes in the marked population at the same time.

23-016

ORIENTATION OF BLACK FLIES (DIPTERA: SIMULIIDAE) TO HOST ODOURS

James Sutcliffe

Department of Biology, Trent University, Peterborough, Ontario, Canada K9J 7B8

Like most other haematophagous insects, black flies combine various host odours with visual and other cues to locate and select hosts. Important host odours for some black flies include carbon dioxide, non-CO₂ breath odours, and body odours. This paper reviews the last fifty years of field research into the nature and role of host odours in black fly host seeking. The following questions are addressed: 1) What roles do host odours have in host location by black flies in different habitats? 2) Are host odours important in determining preferred host species and individual? 3) Are odour cues important in determining the level of black fly attack on different hosts? 4) What mechanisms do black flies use to follow odour plumes?

23-018

Olfactory hostfinding of yellow fever mosquitoes *Aedes aegypti* (Diptera: Culicidae): Synergetic effect of different host odour components.

M. Geier, H. Sass and J. Boeckh

Institut für Zoologie, Universität Regensburg, Germany

In a Y-tube wind tunnel, mosquitoes fly upwind towards host odour sources such as a human hand and also towards an extract obtained by rubbing the hands and feet with a wad soaked in ethanol. If we offer these stimuli in one of the two branches of the Y-tube, we are able to trap 80 to 100 % of the mosquitoes on the test side within 30 sec after stimulus onset. In the most effective dose, the extract is about as attractive to mosquitoes as a human hand. We used this behavioural response as a bioassay to evaluate the attractiveness of liquid-chromatography-fractions of this extract. Lactic acid was confirmed to be a major constituent. Our results demonstrate, that lactic acid is a necessary component for the extract's effectiveness. After its removal, the extract is no longer attractive. However, without the other odour components lactic acid is only slightly effective. This indicates that the extract's high degree of effectiveness is based on a synergism of lactic acid and other odour components. Liquid chromatography of the extract revealed three distinct regions of active fractions. One region contained lactic acid but the effective odours of the other two regions are not identified as yet. A combination of these fractions together with lactic acid is as attractive as the complete extract. These results clearly support an olfactory host recognition using a complex stimulus pattern.

23-017

THE INTERACTION BETWEEN HOST ODOURS AND CARBON DIOXIDE IN HOST SELECTION BY WEST AFRICAN MOSQUITOES

C. Costantini, N.F. Sagnon¹, A. della Torre², M. Coluzzi², J. Brady, G. Gibson

Department of Biology, Imperial College, University of London, UK - 1 Centre National de Lutte contre le Paludisme, Ouagadougou, Burkina Faso - 2 Istituto di Parassitologia, WHO Collaborating Centre, University of Rome 'La Sapienza', Italy

Carbon dioxide is a potent mosquito kairomone, both by itself and, in some cases, as a synergist with other odours -- e.g. L-lactic acid, 1-octen-3-ol. Indeed, no molecules of a potency approaching that of carbon dioxide when used alone, have been discovered so far. The role of other host odours relative to that of CO₂, however, is likely to vary according to the feeding habits of each mosquito species. Strictly anthropophilic malaria vectors as *Anopheles gambiae* s.s., whose odour-mediated host preference for humans has been confirmed, respond to man-derived air-borne cues other than CO₂ more 'effectively' as compared to apparently opportunistic feeders like *Mansonia uniformis*. Nevertheless, CO₂ appears to play an important role for both species in determining how many mosquitoes will eventually approach the odour source. In fact both species show similar dose-response curves for CO₂ in the field; moreover, CO₂ contributes to a large amount of the difference in attractiveness between single human odour-baits. Given the recognised role of CO₂ in the activation and, possibly, upwind displacement of mosquitoes, differences in the amount of carbon dioxide released by a host are likely to have active space/recruitment effects. These are in turn modulated by host odours according to the host selectivity of each mosquito species. Endophagic, nocturnal mosquitoes like *An. gambiae* s.s. and *An. arabiensis* are confronted with a new environment once they have entered the hut where the host(s) sleep(s). Wind is no longer available and visual cues are probably scarce for optomotor anemotaxis; moreover, new short-range physical/chemical cues become accessible. Our experiments in the field have so far dealt only with the outdoor long-range behaviour of mosquitoes, and the results should thus not be extrapolated to include the indoor situation.

23-019

THE EFFECT OF PHYSICAL FACTORS ON HOST-LOCATION BEHAVIOUR OF MOSQUITOES (DIPTERA: CULICIDAE)

W. Takken, B.G.J. Knols, H. Otten

Department of Entomology, Wageningen Agricultural University, Wageningen, The Netherlands

Host-location behaviour of mosquitoes is influenced by physical, visual and olfactory stimuli. Whereas knowledge on the effects of visual and olfactory stimuli is advancing rapidly, the influence of physical factors is poorly understood. This paper describes a laboratory study on the importance of temperature and humidity in host-location behaviour of the malaria mosquito *Anopheles gambiae sensu stricto* Giles. Five day old female *An. gambiae* s.s. were released in batches of 50 at a time in a large two-choice olfactometer. On the upwind side they were collected in glass-container traps, through which pre-conditioned air containing variable stimuli flowed into the observation arena. The response to variations in relative humidity were studied in the presence and absence of odour stimuli. There was no response with relative humidities below 40%. There was a significant response with increasing relative humidity compared to steady state or falling RH's. There was no response to 4.5% CO₂. Mosquitoes responded in large numbers to the emanations of a human hand (hand held in the air stream), but significantly more when RH was increasing than when it was falling or stable. It is concluded that *An. gambiae* s.s. uses a combination of physical and chemical cues in host location, and that slight elevations of moisture above background are required for optimal responses to olfactory cues. The relevance of these findings for field research will be discussed.

A MALE ACCESSORY GLAND PROTEIN MODULATES FEMALE MOSQUITO (DIPTERA: CULICIDAE) HOST-SEEKING BEHAVIOR

J.-J. Lee, M.J. Klowden

Division of Entomology, University of Idaho, Moscow, Idaho USA

The host-seeking behavior of gravid *Aedes aegypti* mosquitoes is modulated by mating and specifically by proteins transferred from the male accessory gland. Using gel filtration, we isolated and identified the component from male accessory glands responsible for this effect of mating. It appeared to be a protein between 5 and 10KDa, which when injected had the same effects on inhibiting host-seeking behavior as did mating.

23-021

PROGRESS IN THE DEVELOPMENT OF A RADAR FOR TRACKING PLUME-FOLLOWING INSECTS.

J.R. Riley, A.D. Smith

Natural Resources Institute Radar Unit, Malvern, UK

Conventional radar is unsuited to tracking insects in low-altitude, plume-following flight, because radar reflections from the ground and from vegetation (clutter) completely obscure the tiny radar echoes from insects. We have therefore attempted to overcome this problem by using the harmonic radar principle. In this technique, the target to be tracked carries an electronic tag which picks up energy from incoming radar pulses, and retransmits some of this energy at twice the radar frequency. This frequency-doubled signal can be detected even in the presence of vastly stronger clutter echoes, and so low-flying targets can be tracked. The technique has the great advantage that no on-board battery is needed, and so extreme miniaturisation of the tag is possible. Initial tracking experiments with electronically tagged bees have been promising¹, and in this presentation we describe progress towards producing a tag for use on smaller insects, such as tsetse flies.

Symposium: Mosquito Producing Wetlands: A United States Problem with Global Implications.

Organizers: W.A. Rowley, R.J. Novak, and J.K. Olson

Moderator: R.J. Novak

ABSTRACT:

Conservation of natural wetland habitats is required to sustain the vitality of the environment as well as to preserve the diversity of animal and plant species supported by these particular kinds of habitats. One hundred and fifty years ago, wetlands were abundant throughout the United States and the world, especially along the major river-drainage systems. However, expansion of agricultural and urban land uses, particularly over the last century, has dramatically reduced the number, diversity, and size of these habitats. The establishment, re-establishment, and maintenance of extensive wetland habitats in proximity to urban and rural communities in ways that will facilitate multi-purpose uses requires the development and implementation of economical sound and environmentally safe mosquito management strategies. These strategies must take into account and ensure not only the protection of human health and quality of life, but also provide for the protection of natural and domestic animals and plants.

The objectives of this Mosquito-Wetlands Symposium are to: 1) present bionomic information on major wetland mosquito species, 2) compare and contrast natural and man-made mosquito producing wetlands ecotypes, 3) discuss mosquito control and associated environmental problems, and 4) present the human and animal health risks associated with mosquito-borne pathogens.

WETLANDS AND THEIR IMPACT UPON VECTOR-BORNE DISEASES

A.B. Knudsen¹, Symposium Mosquito producing wetlands, Robert J. Novak, Organizer

¹Scientist/Medical Entomologist, World Health Organization, Division of Control of Tropical Diseases, Geneva, Switzerland

Historically, wetlands or marshlands have been viewed as areas associated with significant health risks due to an abundance of habitat most propitious for producing mosquito and other disease vectors, resulting in the transmission of malaria, lymphatic filariasis, leishmaniasis, arboviruses, etc.

Today, in some areas of the globe, where there has been favorable bio-rational policies in wetlands regulating man-made environmental changes, wetlands have been improved through appropriate management including effective drainage systems which enable periodic flushing of marshlands, which impacts upon the production of insects of public health concern. Such policies, when correctly applied and used in harmony with the selective use of biocides as an auxiliary control measure is in harmony with wildlife management principles. The results is a bio-healthy wetlands with a reduction in mosquito densities and a natural decline in vector-borne disease transmission.

However, where wetlands or marshlands continued to be administered in the traditional manner in the absence of well planned management guidelines, where flooding occurs periodically accompanied by an increase in pollution and obstruction of drainage, vector breeding is continues and in the absence of a consistent mosquito prevention and control policy, there is an associated increase in disease transmission. This presentation reviews the significance of wetlands, the need to conserve such natural resources while judiciously controlling vectors of disease.

23-029

CONSTRUCTED WETLANDS: THE MOSQUITO PEST AND DISEASE THREATS, AND CONTROL OPTIONS

R.C. Russell

Department of Medical Entomology, University of Sydney and Westmead Hospital, Sydney, NSW 2145, Australia

Increasingly, wetlands are being constructed and used as a process to 'polish' urban storm and waste waters before their disposal into natural water systems.

These 'artificial' wetlands are also seen as an attractive urban asset, providing wildlife refuges and passive recreation areas.

However, mosquitoes exploit such habitats as they do more 'natural' wetlands, and thus can a significant nuisance and potential health risk to nearby residents.

The design of a wetland is critical to its potential for mosquito production; water and vegetation management can be effective for reducing mosquitoes but structural measures for mosquito control often appear incompatible with the objectives and operations of constructed wetlands.

The health issues and disease risks are not inconsequential, however, and should not be dismissed; mosquito surveillance and control should be important objectives in planning, construction and maintenance of wetlands.

This paper will address the issues of mosquitoes and constructed wetlands, with reference to various problems and some case studies in different countries.

23-031

LYME BORRELIOSIS IN EASTERN USA

J.H. Oliver, Jr.

Institute of Arthropodology & Parasitology, Georgia Southern University, Statesboro, GA, USA

Human Lyme disease in eastern North America is caused by the spirochete *Borrelia burgdorferi* sensu stricto. It is transmitted from animals to humans in that region principally by the tick *Ixodes scapularis*. The tick is known to feed on a large variety of mammals, birds, and reptiles. Larvae and nymphs feed on small, medium, and large mammals, birds, and lizards; adults feed on large and medium sized mammals. *Borrelia burgdorferi* has been isolated from several small and medium sized mammal and bird species, however, the mouse *Peromyscus leucopus* is the most important reservoir in the northeastern and north central United States. Other *Peromyscus* species such as *P. maniculatus* and *P. gossypinus* are also excellent reservoirs in areas where they occur. Until recently, Lyme borreliosis was presumed to be absent or rare in the southern USA. The presumption was incorrect. *B. burgdorferi* is widely distributed throughout the south and several enzootic cycles involving several reservoir hosts and tick species are present. Much greater genetic diversity exists among southern spirochetes than among northern strains and there might be several genospecies present. Moreover, a greater diversity of tick species have been found infected. *B. burgdorferi* has been isolated from *I. scapularis*, *I. affinis*, *I. minor*, *I. dentatus*, and *Amblyomma americanum*. Antibodies to *B. burgdorferi* found among several species of animals further confirm the wide distribution of the spirochete in the southern USA.

23-032

BORRELIACIDAL FACTOR IN THE SERUM OF THE WESTERN FENCE LIZARD (*SCELOPORUS OCCIDENTALIS* BAIRD & GIRARD)

R. S. Lane

Department of Environmental Science, Policy and Management, University of California, Berkeley, CA USA

The western fence lizard, *Sceloporus occidentalis* Baird & Girard, is a significant host of subadult *Ixodes pacificus* Cooley & Kohls, the primary vector of the Lyme disease spirochete in the far-western USA. Recent studies have shown that the prevalences of spirochetal infection in host-seeking *I. pacificus* nymphs sometimes exceed those in adult ticks. Experiments were conducted to determine if the reduced spirochetal prevalence in adult ticks is due to a borreliacidal factor in the blood of *S. occidentalis*. Ten *I. pacificus* nymphs having a high prevalence of spirochetal infection (~80%) were put on each of 10 lizards. Five of the lizards had been immunized previously with 10^8 heat-killed spirochetes, the other five lizards served as controls. Following repletion and the transstadial molt, none of the resultant adult ticks from all 10 lizards was found to contain spirochetes. In contrast, infected nymphal ticks that had fed on rabbits passed spirochetes transstadially. In a second trial, motile spirochetes were placed in sera obtained from lizards and several mammalian species. Most spirochetes put in lizard sera died within one hour, whereas those put in mammalian sera survived for up to 72 hours. If spirochetes were put in lizard sera that had been preheated (100 C for 10 min) first and allowed to cool, then they survived for up to 72 hours. I conclude that serum from western fence lizards contains a thermolabile borreliacidal factor. The presence of this factor, and not anti-spirochetal antibodies, appears to be responsible for reducing or eliminating spirochetal infections in *I. pacificus* nymphs that feed to repletion on *S. occidentalis*.

23-034

LYME BORRELIOSIS IN SOUTHERN EUROPE

A.R. Filipe

Instituto Nacional de Saúde, Águas de Moura, Portugal

Ixodes ricinus is the main vector of *Borrelia burgdorferi* in Southern Europe. However, *I. hexagonus* and *I. canisuga* are also involved in enzootic cycles. *Apodemus sylvaticus* is probably the main reservoir of *B. burgdorferi* in Portugal. In one area three strains of *B. burgdorferi* have been isolated from *I. ricinus* and one of them is a new European genomic group (POTi B2). In Portugal no *B. burgdorferi* has been isolated from humans. In some regions from 5% to 12.5% of human population have antibodies against *B. burgdorferi*. The prevalence of cases seems to be around 5% of the human population. On Madeira island *I. ricinus* is infected with *B. burgdorferi sensu stricto*.

In northern Spain isolation of *B. burgdorferi* was made from *I. ricinus* and from a patient with erythema migrans. These strains are *B. burgdorferi sensu lato*. In southern Spain *I. ricinus* parasitizes 30% of wild carnivores and 4% of domestic bovines. Prevalence of spirochetes was from 11% to 28% in *I. ricinus* in northeast Spain. The human population had an antibody prevalence of less than 1% to 38%.

In Italy, *B. burgdorferi* antibodies were detected in 19.5% of asymptomatic rangers and forestry workers. *B. burgdorferi* was isolated from the blood of a patient suffering from a chronic form of polyarthritis in Italy.

In Slovenia 245 cases of Lyme borreliosis were registered in 1986.

The situation in Greece is not well known. However, three humans from Crete had antibodies to *B. burgdorferi*.

23-033

LYME BORRELIOSIS IN WESTERN, CENTRAL AND NORTHERN EUROPE.

L. Gern, Institut de Zoologie, University of Neuchâtel, Switzerland

Lyme borreliosis (LB) is considered to be the most prevalent tick-borne disease in temperate areas of the Northern hemisphere. In Europe, unlike the United States, LB is not a notifiable disease and therefore our knowledge of the epidemiology of LB in this area is limited. The distribution of LB is correlated with the distribution of its main vector *Ixodes ricinus*.

European LB can be caused by three different genomic species: *Borrelia burgdorferi* (Bb) sensu stricto, *B. garinii* and *B. afzelii*. The division in genomic groups seems to have clinical relevance for LB in Europe.

Characterization of tick isolates of Bb suggests that Bb sensu lato contains more than three genomic species. Studies have demonstrated that various genospecies are present in the tick population of one endemic area and also that simultaneous infection by more than one genospecies can be detected in *I. ricinus* ticks.

Small rodents, birds, squirrels, hares and hedgehogs have been reported as reservoir hosts for Bb s.l. in Europe.

Bb has been detected in other tick species than *I. ricinus* but the role of most of them in the ecology of the disease remains unclear. However, *I. hexagonus* and *I. uriae* are able to maintain enzootic transmission cycles involving hedgehogs and sea-birds. The potential public health significance of the presence of Bb in these tick species, in areas where the bridge vector *I. ricinus* is absent, remains unclear.

23-035

LYME BORRELIOSIS IN THE FORMER SOVIET UNION Yu.S. Balashov

Zoological Institute RAS, St. Petersburg, 199034, Russia

In the area former Soviet Union Lyme borreliosis is spread throughout the entire forest zone from the western boundary up to the Pacific coast. The northern and southern boundaries of borreliosis are determined by geographic distribution ranges of vector ticks. The major vectors of borrelia to man are adults *Ixodes ricinus* and *I. persulcatus*. Most aggressive in attacking man is *I. persulcatus*. The season of borrelia transmission is determined by the period of activity of adults and coincides with May-July; in the areas of *I. ricinus* distribution it continues in August-September. Nymphs attack man much less frequently than adults. In the enzootic cycle of the pathogen participation of other close species of the genus *Ixodes* is possible.

Preimaginal phases of the first two species parasitize on several dozens of species of small mammals and birds and adults parasitize on average and large mammals. Borrelia were found on ticks using methods of dark field and phase contrast in many regions. Infestation of ticks varied from low percentage up to 80-90% and higher. Among mammal hosts borrelia were obtained from a few species of rodents and shrews. Borrelia were identified to a species in rare cases. *Borrelia burgdorferi sensu strictum*, *B. afzelii*, and *B. garinii* were found in ticks. These pathogens were found in both species of vectors and frequently in the same locality. Morphological techniques permitted to establish a great polymorphism in shape and sizes of borrelia in ticks. Localization, number and shape of borrelia in many cases depends on the stage of tick development.

23-036

LYME BORRELIOSIS IN JAPAN

K. Miyamoto

Department of Parasitology, Asahikawa Medical College, Asahikawa, 078, Japan

Since the first case of Lyme borreliosis (LB) was reported in Japan (1987), the total estimated number is about 100 cases until present time.

Almost all of those cases showed milder symptoms than the cases in the United States and /or Europe.

The cases appeared between April and August, reaching a maximum in June at Hokkaido. The LB of the patients was caused by infestation of adult female *Ixodes persulcatus* infected with *Borrelia burgdorferi* sensu lato.

In the spring, many people harvest edible plants in the field, and harvesters bring back the plants to their home together with infected ticks.

During an enzootic cycle the spirochetes are transmitted from the reservoirs (*Apodemus* mice, *Clethrionomys* vole and *Turdus*, *Emberiza* migratory birds) to another normal host by immature stage of *I. persulcatus* tick as an important vector.

No transovarial transmission of the agent of LB was observed.

The agents had been isolated from the erythema caused by tick bite in 19 LB patients removed infested ticks from their skin by themselves by using fingers before therapy.

23-038

SALIVARY GLAND ANTICOAGULANTS IN VECTOR MOSQUITOES (DIPTERA: CULICIDAE)

A.A. James, K.R. Stark

Department of Molecular Biology and Biochemistry, University of California, Irvine, California, USA.

Virtually all hematophagous arthropods salivate powerful anticoagulants, vasodilators, and platelet anti-aggregating factors that facilitate hematophagy. Anticoagulants in a number of important vector mosquitoes were demonstrated by a delay of coagulation of human plasma in the presence of female adult salivary gland extracts. Salivary gland extracts from all mosquitoes species examined caused a significant delay of the recalcification time, the prothrombin time, and the activated partial-thromboplastin time, indicating that they all exert their effects on the common coagulation pathway. Chromogenic assays to determine the coagulation inhibition site were performed for coagulation factor Xa (FXa) and thrombin, the major components of the common pathway. In a remarkable finding, all anopheline mosquitoes have thrombin-directed anticoagulants and the culicine mosquitoes have FXa-directed anticoagulants although variation exists in the degree of inhibition. For example, in the Yellow Fever mosquito, *Aedes aegypti* (L), the anticoagulant has been shown to result from the specific inhibition of FXa based on a FXa clotting assay and the inhibition of FXa-directed cleavage of the synthetic chromogenic substrate, chromozym X. The inhibition of FXa by female salivary gland extracts exhibits non-covalent, noncompetitive inhibition kinetics, and is reversible. We propose that the *Ae. aegypti* anticoagulant is a novel, proteinaceous serine protease inhibitor specific for FXa. The differences in the site of action of the anticoagulants most likely reflects the long period of independent adaptation of the two hematophagous mosquito subfamilies to the challenges presented by vertebrate hemostasis.

23-037

LYME BORRELIOSIS - A GLOBAL PERSPECTIVE: DISCUSSION, SUMMARY AND CONCLUSIONS.

T.G.T. Jaenson

Department of Entomology, Swedish University of Agricultural Sciences, P.O.Box 7044, S-750 07 Uppsala; and Department of Zoology/Zoological Museum, Uppsala University, Villavägen 9, S-752 36 Uppsala, Sweden

During this symposium on Lyme borreliosis, the presenting speakers will focus on the following topics: enzootic cycles; bridge (link) vectors between natural reservoirs and humans; genetic heterogeneity of *Borrelia burgdorferi* sensu lato; and the geographic distribution of the vectors (*Ixodes* spp.). Some of the main areas of frontline research related to the ecology and epidemiology of Lyme borreliosis during the next few years will be to investigate and explain:

. The geographic distribution of the different genomic species in the *B. burgdorferi* s.l. taxon, and the possible enzootic occurrence of this taxon and/or closely related taxa causing human "Lyme disease" in the Neotropical, Ethiopian and/or Australian region(s).

. The role of birds in the maintenance and dissemination of *B. burgdorferi* s.l.

. Factors determining the association between certain genomic species of *B. burgdorferi* s.l. and particular vertebrate reservoir species.

. The intrinsic biochemical and physiological factors determining competence or incompetence of potential vectors to transmit *B. burgdorferi* s.l.

. The development of mathematical transmission models to explain the dynamics of Lyme borreliosis in different geographic (climatic) regions, and mathematical models capable to predict human Lyme disease risk. In this context much research is needed to comprehend how various environmental parameters determine the geographically variable seasonal dynamics of the *Ixodes* vector populations.

VARIATION IN THE VASODILATORY ACTIVITY OF SALIVA AMONG POPULATIONS OF THE SAND FLY, *LUTZOMYIA LONGIPALPIS*.G.C. Lanzaro¹, A. Warburg², J-P Mutebi¹ and J.M.C. Ribeiro³

Center for Tropical Diseases, Department of Pathology, University of Texas Medical Branch, Galveston, TX USA-1, Department of Parasitology, Hadassah Medical School, Hebrew University, Jerusalem, Israel-2, Department of Entomology, University of Arizona, Tucson, AZ USA-3

The sand fly, *Lutzomyia longipalpis* is the vector of *Leishmania donovani chagasi* in Latin America. Working with three colonies, from Brazil, Colombia and Costa Rica, we conducted a series of studies which demonstrated that these three populations represent distinct species and that these species differ in the erythema producing quality of their saliva, with the bite of the Costa Rican species producing little or no erythema. We showed that this difference involves the vasodilatory peptide, maxadilan. We successfully cloned the maxadilan gene from each of the three putative species. An analysis of the nucleotide sequence from each species showed consistent differences between species and polymorphisms within species. Recombinant maxadilan was produced for each species and recombinant peptides were assayed for vasodilatory activity. All were found to have equivalent vasodilatory activity. These results suggest that the difference between Costa Rican flies and the others is not in the vasoactivity of the maxadilan peptide, but rather in the levels of expression of this gene. The occurrence of a fly species with limited vasodilatory activity in its saliva in Central America (Costa Rica) is coincident with a non-visceralizing disease produced by *L.d. chagasi*, which normally produces visceral leishmaniasis. We hypothesize that the development of visceral disease is influenced by the presence or absence of vasodilator in the vector saliva.

23-040

ANALYSIS OF BLACK FLY SALIVA AND ITS' RELATIONSHIP TO VECTOR STATUS

M. S. Cupp, E. W. Cupp

The vector capacity of medically-important *Simulium* species (black flies) is directly related to its' ability and propensity to blood-feed on humans. Because of the critical role of blood-feeding to vector status, we are analyzing and comparing pharmacological properties of black fly saliva from several species to identify activities that may be critical for vector competence.

Salivary glands extracts (SGEs) were prepared by salivary gland homogenization and centrifugation. The SGEs of all species examined contain potent vasodilative activity that was demonstrated by skin hyperemia following intradermal injection in the shaved skin of New Zealand White (NZW) rabbits. Total gland activity of the highly anthropophilic (human seeking), filarial parasite-transmitting vector from Guatemala, *S. ochraceum*, was an order of magnitude greater than that of other species examined. A 15.3 Kda protein that produced hyperemia in the test assay was isolated from a laboratory colonized species, *S. vittatum*. Protein sequence information was used to isolate a cDNA clone and recombinant protein was produced in a baculovirus expression system. Studies are underway to elucidate the mechanism of action of this vasoactive protein and to examine its' relationship to vector status.

Assays of SGE apyrase activity were conducted to examine the relative proportions of ADP/ATP degrading action in black fly salivary glands. In addition to quantitative differences, qualitative biochemical properties of this enzyme activity differed among species indicating that these SGE protein(s) have species-related structural variations in the Simuliidae.

Inhibition of blood coagulation for these pool-feeding insects may also be an important contributor to vector competence. Three different proteins were identified that target specific components in the coagulation cascade focused at the common final pathway. Two of these proteins prevent action of the prothrombinase complex by inhibiting both factor Xa and factor V, while the third SGE protein blocks the catalytic activity of thrombin. Differences in these activities among black fly species correlate with host preference and thus may indicate a role in vector competence.

23-042

SUPPRESSIVE EFFECTS OF *IXODES RICINUS* SALIVARY GLAND EXTRACT ON NONSPECIFIC ANTIVIRAL IMMUNITY

J. Kopecký

Institute of Parasitology, Czech Academy of Sciences, České Budějovice, Czech Republic

Tick saliva has been shown to contain molecules with immunosuppressive activities. There is increasing evidence that the nonspecific suppression of host immunity by tick saliva is exploited by tick-borne pathogens, e.g. arboviruses. We demonstrated a suppressive effect of the salivary gland extract (SGE) derived from partially fed *Ixodes ricinus* females on two important nonspecific antiviral mechanisms: interferon and natural killer (NK) cells.

SGE decreased cytotoxic activity of nonstimulated and *in vivo* polyinosinic-polycytidylic acid (poly I:C)-stimulated NK cells by 31% and 28%, respectively. NK cells stimulated *in vitro* by lipopolysaccharide (LPS) were markedly inhibited (74% suppression), while concanavalin A (Con A)-stimulated NK activity was not affected by SGE.

SGE profoundly decreased the interferon production induced by polyI:C *in vitro* (94% suppression), whereas its effect on LPS-stimulated splenocytes was less pronounced (62% suppression). Con A-stimulated splenocytes were resistant to the inhibitory effect of SGE.

Treatment of P388D1 macrophage cell line by SGE accelerated replication of tick-borne encephalitis virus in these cells early after infection, probably due to inhibition of interferon induction.

23-041

A LECTIN IN SALIVARY GLANDS OF THE TICK *IXODES RICINUS*: DETECTION AND PARTIAL CHARACTERIZATIONL. Grubhoffer^{1,2} and E. Durnová²

¹Institute of Parasitology, Academy of Sciences of the Czech Republic - ²Faculty of Biological Sciences University of South Bohemia, České Budějovice, Czech Republic

Lectins are a structurally diverse class of proteins, their only common features being the ability to bind carbohydrates specifically and reversibly. They act as mediators of cell recognition in a wide range of biological systems including those of vector-pathogen.

Hemagglutinating activity (HA) was demonstrated and characterized in *Ixodes ricinus* salivary gland (SG) extracts. The highest HA was observed using mouse red blood cells. In a hemagglutination inhibition test the SG HA showed binding affinity to N-Acetylneuramic acid, D-Fructose, L-Rhamnose, D-Trehalose and several glycoconjugates. Mouse polyclonal antibodies were raised against this HA fractions; they have been used to identify a SG protein with a molecular weight of 70 kDa. New SG lectin may play a role in transmission of the tick-borne encephalitis virus and borrelia spirochetes.

23-043

DEATH AND DIFFERENTIATION OF TRYPANOSOME INFECTIONS IN TSETSE

Susan C. Welburn & I. Maudlin. Division of Molecular Genetics, Institute of Biomedical and Life Sciences, University of Glasgow, Anderson College, 56 Dumbarton Road, Glasgow, G11 6NU, U.K.

Trypanosoma brucei rhodesiense undergoes complex morphological and biochemical changes during its life-cycle in insect (tsetse fly) and vertebrate hosts. Parasites alternate between proliferative and non-proliferative phases to co-ordinate establishment in and transition between different host environments. Transformation from bloodstream form to insect (procyclic) forms in tsetse is rarely successful, most infections fail to establish in the midgut and the parasites die. Those which evade death form a persistent immature infection in the midgut where they wait for the opportunity to mature and complete their life cycle - again very few infections successfully undergo maturation (migration to the salivary glands and differentiation to mammalian infective form) and complete their life cycle. It appears that death and differentiation are closely linked in this parasite as parasite death during establishment can be prevented by inhibition of a lectin in the fly midgut; continuous inhibition of this lectin also blocks maturation suggesting that the lectin is utilised by the parasite to provide a signal for differentiation. Recent results suggest that lectins may signal trypanosomes to activate a cell suicide pathway similar to the process of apoptosis (a form of programmed cell death previously described in metazoa) and that such a mechanism may operate to promote and maintain homeostasis and genetic stability within a population. Electron micrographs of lectin treated trypanosomes *in vitro* and *in vivo* reveal surface membrane vesiculation and migration of chromatin to the periphery of the nuclear membrane. Examination of the DNA of *in vitro* treated trypanosomes shows the characteristic fragmentation of DNA into oligonucleosome sized pieces. The response of parasites to external signals leading to apoptosis are probably as varied as those in metazoa.

MOLECULAR ASPECTS OF INTERACTIONS BETWEEN ANOPHELES TESSELLATUS AND THE HUMAN MALARIA PARASITES PLASMODIUM VIVAX AND P. FALCIPARUM.
M.S. Ramasamy¹, K.A. Srikrishnaraj¹, R. Kulasekera¹, I.C. Wanniarachchi², R. Ramasamy²

¹Vector Biology and ²Molecular Biology Laboratories, Institute of Fundamental Studies, Hantana Road, Kandy, Sri Lanka.

Rabbit antibodies to whole midgut tissue of *Anopheles tessellatus* ingested in an infective bloodmeal reduced the infectivity of *Plasmodium vivax* to the vector in a complement independent manner. Antibodies raised to midgut glycoproteins also mediated a transmission blocking effect, suggesting that glycoproteins of the midgut and of the peritrophic membrane play a role in ookinetes traversing the midgut.

Trypsin produced in the midgut of the vector influenced malaria parasite infectivity as shown by the effects of feeding trypsin inhibitors in an infective bloodmeal. Inhibiting midgut trypsin activity increased the infectivity of *P. vivax* and decreased the infectivity of *P. falciparum* to the vector. This probably reflects specific differences in the biology of the two human malaria parasites within the mosquito midgut. The times of ookinete formation, midgut penetration and the requirements for chitinase may be relevant factors that differ between *P. vivax* and *P. falciparum*.

23-046

VECTOR COMPETENCE MECHANISMS ASSOCIATED WITH TICK SALIVA

T.N. Mather, M.T. Yeh, J.M.C. Ribeiro¹

Center for Vector-Borne Disease, University of Rhode Island, Kingston, RI USA-1 Department of Entomology, University of Arizona, Tucson, AZ USA

Vector competence in tick-transmitted Lyme borreliosis is determined by both physiologic and ecologic mechanisms. Anti-complement activity in the saliva of vector ticks (*Ixodes scapularis*), but lacking in non-vector ticks like *Dermacentor variabilis* appears to protect *Borrelia burgdorferi*, the Lyme borreliosis agent, from complement-mediated killing in the tick's midgut. Another ixodid tick, *Amblyomma americanum* exhibited variable salivary anti-complement activity, but rarely feeds on infectious hosts, thereby avoiding infection. Salivary anti-complement activity may be important in protecting other tick-transmitted pathogens from immune killing within the vector.

23-047

THE SENSORY PHYSIOLOGY OF HOST-SEEKING, HOST-ACCEPTANCE, MATING AND OTHER BEHAVIOURS OF BLOOD-SUCKING ARTHROPODS
P. Guerin, P. Steullet, C. McMahon, J. Taneja, P. Guerenstein, T. Kröber, M. de Bruyne, S. Grenacher, M. Dougherty and P.A. Diehl
Institute of Zoology, University of Neuchâtel, Rue Emile-Argand 11, 2007 Neuchâtel, Switzerland

Chemostimuli are employed by ectoparasitic arthropods to guide them in a variety of vital behaviours such as host seeking and acceptance, feeding, mating, oviposition and selection of a refuge. Volatile chemostimuli involved in host-seeking have been most extensively studied by us for ticks. Despite the limited number of olfactory receptor cells in wall-pore sensilla on the first leg-pair, ticks are well equipped for host odour perception with olfactory receptors for CO₂, sulfides, aliphatic aldehydes, aromatics, lactones and fatty acids. Studies on the behavioural responses of triatomines to host odours have taught us that although these insects mostly walk to hosts, they employ strategies for host location similar to those employed by male moths when flying upwind to a female in a pheromone plume. Gustatory stimuli govern a variety of responses. The behavioural responses of ticks to steer-hair and its chemical constituents clearly demonstrate the role for contact chemostimuli in host recognition and acceptance. Regular sampling of the substrate with sensilla on legs and mouth-parts precede attachment for a blood-meal, and chemoreceptors housed in these sensilla are sensitive to a range of skin products. Receptors for gustatory stimuli involved in the tick mating process are carried on the same appendages. In addition to these host-associated behaviours, this exposé will also treat the role of natural products in refuge selection by triatomines and oviposition in phlebotomes.

23-048

TICK SALIVARY SECRETIONS AT THE TICK-HOST INTERFACE

J. R. Sauer, A. S. Bowman, L. B. Coons¹, G. R. Needham²
 Department of Entomology, Oklahoma State University, Stillwater, OK, USA-1 Department of Biology, University of Memphis, TN, USA-2 Department of Entomology, The Ohio State University, Columbus, OH, USA

The problems associated with prolonged attachment to the host necessitates that ticks produce and inject substances to counter host defense mechanisms. The saliva of engorging ticks is rich in bioactive components that includes an impressive variety of pharmacological properties. Factors identified in the saliva include a mostly proteinaceous cement to help anchor the mouthparts to the host, various enzymes and enzyme inhibitors, histamine agonists and antagonists, anticoagulants, antiplatelet factors and protein immunomodulating factors. Other factors include prostaglandins and a novel caireticulin. These factors are believed to be major reasons for the biological success of ticks and their ability in vector pathogenic organisms, a list that includes viruses, fungi, rickettsiae, bacteria and protozoa.

GLOBAL DISTRIBUTION OF *Aedes albopictus* AND ITS CONTINUING SPREAD AT THE APPROACH OF A NEW MILLENNIUM

A.B. Knudsen¹, Invited speaker, Symposium on *Aedes albopictus*, Carl J. Mitchell and Giancarlo Majori, Organizers
¹Scientist/Medical Entomologist, World Health Organization, Division of Control of Tropical Diseases, Geneva, Switzerland

Aedes albopictus, an important *Stegomyia* species is probably best known to the public and media by its fanciful nick name, the Asian "Tiger Mosquito". This colorful *Aedes* mosquito gained notoriety as an aggressive day time biting, nuisance mosquito in the early 1980's when it began its invasion of the Americas. Today we recognize that the saga of the continuing adaptation and spread of this species into new regions and countries around the globe is the most dramatic account of an introduction of a medically important insect species in the 19th century.

Aedes albopictus has now been reported from more than 53 countries, including at least 24 states or territories of the United States. It was introduced into Brazil independent of the USA in 1986 and is reported to be present in at least seven states and nearly 673 counties and municipalities. It has spread southward from the USA into Mexico, to the Dominican Republic in the Caribbean and more recently it has been reported in Guatemala and Honduras. In Europe, it is present in Italy in ten regions and 19 provinces, threatening other southern European countries. Its introduction into West Africa as reported by Nigeria indicates that it has already spread to five states. This paper discusses the continuing spread and importance of the mosquito which ranks second only to *Aedes aegypti* in its importance as a vector of dengue and dengue haemorrhagic fever.

23-051

PRESENT DISTRIBUTION OF *Aedes albopictus* IN ITALY: POSSIBILITIES OF CONTROL AND FURTHER SPREAD.

G. Majori¹ and R. Romi

Invited speaker, Symposium on *Aedes albopictus*, Carl J. Mitchell and Giancarlo Majori, Organizers.

¹Istituto Superiore di Sanità, Laboratory of Parasitology, Rome, Italy.

Since 1991, when the first breeding population of *Aedes albopictus* in Italy was reported (Dalla Pozza e Majori, 1992), efforts to control the spread of the species were undertaken. All the known infestations of the species were controlled by employing larvicides and adulticides, and the local spread was carefully monitored, so that mosquito populations could be seasonally strongly reduced but not eradicated. A surveillance system, integrated into the structure of the National Health System, was quickly activated. However before 1993 most of the infestation have been detected by passive reporting, while after that year have been detected by active research in the "at risk" sites of the different regions. At present stable colonies of *Ae. albopictus* are reported in 10 regions and 19 provinces of our country (January, 1996).

As the importation in Veneto region of *Ae. albopictus* eggs infested tires from Atlanta (USA) was proved in 1992 (Dalla Pozza et al., 1994). Since then attempt to get a national regulation about importation of used tires from "at risk" countries were made. However data from ISTAT (Istituto Nazionale di Statistica) show most of the used tires imported between 1990 and 1994 were coming from CEE or European countries (meanly less than 2% of the total was coming from unidentified countries, not necessarily infested by *Ae. albopictus*).

Since late 1991 regional and local rules were made to control the infestations in the tire deposits. Despite this fact, the internal trade of used tires from Veneto region has been the source of infestation of the other Italian regions. Infact most of the infestation in our country originated in deposit of used tires. As a new colonization of *Ae. albopictus* generally involve a few individuals, the population of the insect can reach a detectable density only after some seasons of breed. Probably, for this reason, also the infestation detected by active research in the last 2 years originate from tire loads purchased before 1992-93.

23-052

THE ROLE OF *AEDES ALBOPICTUS* (SKUSE) AS AN ARBOVIRUS VECTOR (DIPTERA: CULICIDAE)

C.J. Mitchell

Division of Vector Borne Infectious Diseases, National Center for Infectious Diseases, Centers for Disease Control, U.S. Public Health Service, Fort Collins, Colorado, USA

During the past two decades *Aedes albopictus* has extended its range, largely through the transport of drought-resistant eggs and/or aquatic stages in used tire casings, to parts of North, South, and Middle America, the Caribbean, Africa, Southern Europe, and some previously uninfested Pacific Islands. This remarkably rapid spread of a mosquito species is unprecedented during this century and has heightened concerns among public health and vector control officials because of the known and potential vector relationships of *Ae. albopictus* with several arboviruses of public health and veterinary importance. *Aedes albopictus* is an established vector of dengue (DEN) viruses in parts of its range, and is a competent vector for a wide variety of arboviruses under experimental conditions. In addition to DEN viruses, *Ae. albopictus* has been found naturally infected with Japanese encephalitis virus (in Asia) and with eastern equine encephalitis, Keystone, Potosi, and Tensaw viruses (in the USA). The results of field and laboratory investigations concerning the known and potential vector relationships of *Ae. albopictus* for approximately two dozen arboviruses will be summarized and discussed.

23-054

THE SITUATION OF *AEDES (STEGOMYIA) ALBOPICTUS* (SKUSE, 1894) IN BRAZIL

I. A. Braga¹

¹Gerência Técnica de Entomologia e Pesquisa Operacional - Fundação Nacional de Saúde - Ministério da Saúde- Brasil

The mosquito *Aedes albopictus* was detected for the first time in Brazil in May 1986 in the state of Rio de Janeiro (located in the southeast of the country), and soon afterwards was found in the states of Espírito Santo and Minas Gerais, also in the southeast.

Although *Aedes albopictus* in Brazil has the capacity to transmit dengue virus, there have not been any outbreaks of dengue in areas where this species is present in the absence of *Aedes (Stegomyia) aegypti* (Linnaeus, 1752)

In 1992, Serufo reported the isolation of virus from larvae of *Aedes albopictus* from the city of Campos Altos, state of Minas Gerais, where *Aedes aegypti* had not been detected. During this same period three cases of dengue were registered in this city. Subsequently, the Virology laboratory of the Evandro Chagas Institute contested these results because in tests done in their laboratory none of these patients was found with serology positive for dengue virus.

In counties where both species coexist, there are many reports of epidemics, but it has never been possible to isolate dengue virus from *Aedes albopictus* mosquitos during these outbreaks

Therefore, although it is possible, until now transmission of dengue by *Aedes albopictus* has not been proved in Brazil

Aedes albopictus is now found in 7 of the 27 Brazilian states, distributed mainly in the southeastern region (Sao Paulo, Minas Gerais, Espírito Santo and Rio de Janeiro) and the south (Parana), and also in Maranhao (northeast) and the Federal District of Brasília (midwestern region).

Aedes albopictus is found in 876 (42,6%) of the 2058 counties in these 7 states. In the southeastern region, the principal area of concentration. 800 (50,8%) of the 1573 counties are positive for this species. In 169 (19,3%) counties in the area infested by *Aedes albopictus*, it occurs in the same county as *Aedes aegypti*¹

CONTROL OF *AEDES ALBOPICTUS* (SKUSE) (DIPTERA: CULICIDAE) AND PERSONAL PROTECTION

D.R. Barnard, R. Xue, C. E. Schreck

Medical and Veterinary Entomology Research Laboratory, Agricultural Research Service, U.S. Department of Agriculture, Gainesville, Florida 32604, USA

Aedes albopictus larvae are susceptible to organophosphate (OP) and pyrethroid insecticides, insect growth regulators (IGRs), and *Bacillus thuringiensis israelensis*. IGRs are more toxic to larvae than pyrethroids and OPs. In Asia, resistance to DDT is widespread, though variable, and malathion tolerance/resistance is reported in North America. Delivery of larval controls to outdoor habitats is difficult but slow release formulations of methoprene and temephos in tire casings result in 100% larval mortality for 150 and 360 days, respectively. Adults are susceptible to OP, carbamate, and pyrethroid insecticides applied mainly by ground ULV. Cyclopoid copepods, predatory mosquitoes (*Toxorhynchites* spp.), protozoans, bacteria, fungi, and fire ants are potential biological control agents. Source reduction is effective if container collection and removal programs are extensive and ongoing. Small scale eradication of *Aedes albopictus* in the urban setting has been achieved by combining chemical control with strict source reduction measures. Personal protection methods comprise mosquito avoidance, the use of physical barriers, such as mosquito netting and/or permethrin-treated clothing, and repellents. Repellent products containing >12% deet (N,N-diethyl-3-methylbenzamide) provide protection from bites by *Aedes albopictus* for 6 hours or longer.

23-055

REPRODUCTIVE PHYSIOLOGY OF *AEDES ALBOPICTUS* (DIPTERA: CULICIDAE)

H. Briegel & S. E. Timmermann

Zoologisches Institut der Universität Zürich, Zürich / Switzerland

Aedes albopictus is in the process of colonizing subtropical and temperate climates around the globe. Since it represents a potential vector of various arboviruses we have initiated a comparative investigation of its reproductive physiology at two temperature settings, 32°C versus 17°C. The respective isotherms are assumed to approximate the possible range of continuous breeding for this species.

Developmental time from hatching until eclosion varies between 8 days (17°) and 25-50 days (32°). These temporal differences are also reflected in the corresponding body sizes. The range of female wing lengths is 2.9-3.3 mm when raised at the high temperature and 3.4-3.7 mm at the lower temperature. For males the range of wing length is 2.3-2.8 mm at 32°C and 2.7-3.2 mm at 17°C. The average protein, lipid, and glycogen content of newly eclosed females and males does not differ significantly between the two temperatures. When related to body size however, the caloric contents clearly increase in both sexes when reared at the higher temperature.

The effects of starvation or of sugar-feeding are followed in terms of survivorship curves and by quantitative analyses of glycogenesis and lipogenesis.

The volume of blood consumption on a human host and female fecundity unexpectedly do not correlate with body size, but appear to depend on environmental temperatures. Quantitative aspects of blood meal utilization for oogenesis will be presented together with the duration of the gonotrophic cycle under these different temperatures.

These data shall provide a picture of the adaptability of this species to various climatic conditions outside its original geographic occurrence and to better understand its colonisatory success.

Supported by the Swiss National Science Foundation.

UTILIZATION OF LOW ALTITUDE REMOTE SENSING IMAGERY TO DETECT LARVAL HABITATS OF

TIRE-BREEDING MOSQUITOES G. M. Beavers, F. W. Knapp¹

United States Navy Medical Research Unit Number Three, Cairo, Egypt - 1 Department of Entomology, University of Kentucky, Lexington, KY USA

Improperly stored vehicle tires serve as an excellent breeding habitat for several mosquito species that vector a number of human and animal diseases. The commercial trade of used tires is also considered to be responsible for the introduction and spread of several mosquito species including the Asian tiger mosquito, *Aedes albopictus* (Skuse). Improperly stored or illegally dumped tires are clearly a public health concern. Locating tire piles is currently time consuming, labor intensive and generally ineffective. Remote sensing, particularly the use of multispectral video imagery obtained from aircraft, may be a viable alternative for detecting tire piles. Measurements of the spectral reflectance of tires and various background land coverages were acquired in the range of 350-2500 nanometers (nm) at 2 and 4 nm bands using a portable spectroradiometer. The best spectral regions for differentiating tires from background coverages were selected for data collection. Video imagery of tire piles varying in size from approximately 50 tires to 3 million, and located in rural and urban environments were acquired at altitudes of approximately 150,300 and 500 meters above ground level at three different spectral wavelengths. Individual video frames containing the tire sites were then digitized for computerized image analysis and both supervised and unsupervised classification algorithms were used in the analyses. Results of these analyses will be discussed.

23-058

SUSCEPTIBILITY LEVELS OF ITALIAN *Aedes albopictus* AFTER 3 YEARS OF ADULT AND LARVAL CHEMICAL CONTROL.

R. Romi and G. Majori

Istituto Superiore di Sanità, Laboratory of Parasitology, Rome, Italy.

Field population of *Aedes albopictus*, collected in Liguria, Veneto and Emilia-Romagna regions, were tested for determining the susceptibility levels to the most common insecticides employed in larval and adult control. *Ae. albopictus* samples were collected respectively in 1) urban area of Genoa; 2) urban area of Padua; 3) Abano, a town in province of Padua; 4-5) Calderara di Reno, a town in province of Bologna.

Larval and adult susceptibility tests were carried out according to the standard WHO method (WHO/VBC/81.805 and 81.806), employing the suggested diagnostic concentrations (WHO, Tech. Rep. Series, 86.737).

Batches of third/early-fourth instar larvae were exposed to different concentrations of temephos (between 0.001 and 0.02 mg/l) and chlorpyrifos (0.0005-0.01 mg/l). Batches of adult females were exposed to diagnostic dosages of permethrin (0.25%), deltamethrin (0.025%) and propoxur (0.1%). Results were compared with the baseline data on insecticide susceptibility obtained in 1992 on *Ae. albopictus* population from Padua.

All larval and adult populations tested were found fully susceptible to the discriminant dosages of the 5 insecticides used. Temephos (0.02 mg/l) and chlorpyrifos (0.01 mg/l) gave 100% larval mortality. Deltamethrin and propoxur provided 100% adult mortality after one hour of exposure; permethrin provided 90-96% mortality after one hour and 100% mortality after 2 hours.

However, comparing the values of LD50 of the populations tested with the 1992 baseline data, a decrease in the susceptibility to the antilarval temephos and chlorpyrifos was observed in 2 of the populations studied.

23-057

DENGUE AND DENGUE HEMORRHAGIC FEVER (DHF) IN CHINA — VECTORS AND CONTROL

Jin-tong ZHANG and Rong-man XU

Department of Vector Biology and Control, Institute of Microbiology and Epidemiology, AMHS, Beijing 100071, CHINA

Since the end of seventies this century, with two peak epidemics during 1979-1981 and 1986-1987, the reprevallence of dengue has swept the coast areas of southeastern China after some 30 years of ceasing. From 1978 to 1995, over 670 thousand cases have been found in Guangdong, Guangxi, Hainan and Taiwan Provinces, with 490 deaths. Although *Aedes aegypti* is the main vector to dengue, the Asia tiger mosquito *Aedes albopictus* has played an important part not to be ignored. It's believed that some 38 thousand cases might be the victims of *Ae. albopictus* during the period of 1978-1993.

Integrated management (IM) with community participation (CP) has been emphasized in vector control programmes. Since 1990 *Ae. aegypti* has been wholly swept from some of the towns and villages along the coast of Guangxi Province by the implementation of IM strategy including the release of culicivorous fish to the containers and the prompt elimination of the temporary gathered water. With the active participation of well-organized residents, and by the health education, the hostesses successfully managed their habitations, Breteau Index (BI) declined by 97.4% in 112 villages of Chengmai County, Hainan Prov. Organized and supported by the local authorities and Canada's International Development and Research Center (IDRC), it's now in planning and programming to eliminate *Ae. aegypti* from the whole Hainan Island in a few years.

OPERATIONAL APPLICATION OF VARIOUS IDENTIFICATION TECHNIC OF VECTORS AND PARASITES OF ONCHOCERCIASIS IN WEST AFRICA

Akpoboua L.K.B., Bissan Y¹., Toé L²., and Hougard J.-M³. Onchocerciasis Control Programme In West Africa, Ouagadougou, Burkina Faso - 1 Onchocerciasis Control Programme in West Africa, Ouagadougou, Burkina Faso - 2 Onchocerciasis Control Programme In West Africa, Bouaké, Côte d'Ivoire - 3 Onchocerciasis Control Programme in West Africa, Ouagadougou, Burkina Faso.

Technics using cytological method and morphological characteristics other than wing tuft colour have provided valuable information about the taxonomy and the dynamics of the *Simulium damnosum* flies. A more recent molecular biology technic using the heteroduplex analysis of DNA has allowed the identification of all stages from egg to adult of *Simulium damnosum* complex from small fragments (part of antenna, etc) leading to a more accurate estimate of the vector capacity of the various species and a better management of the resistance phenomenon by rotational use of larvicides.

In collaboration with the onchocerciasis control programme (OCP), the development of DNA probes specific to *Onchocerca volvulus* and *O. ochengi* and furthermore to savanna and forest strains of *O. volvulus* by Dr Unasch from the University of Alabama in Birmingham has been a major contribution in the assessment of the transmission due only to *O. volvulus*. As part of this collaboration, the same author recently developed the technic of blackflies pools screening by polymerase chain reaction (PCR) for the infection prevalence assessment. This new technic will help in the detection of any recrudescence of infection in oncho free zones.

MOLECULAR APPROACHES TO THE DIAGNOSIS OF ACARICIDE RESISTANCE IN THE CATTLE TICK *BOOPHILUS MICROPLUS*

K.R. Gale, N. Liddicut & D. Kemp

CSIRO Division of Tropical Animal Production, Brisbane, Australia

Since the cattle tick *Boophilus microplus* was introduced into Northern Australia in 1872, it has extended in distribution into most tropical and sub-tropical high rainfall areas and has developed resistance to a broad spectrum of acaricides. The continued use of a limited number of available acaricides is necessary to sustain efficient cattle production. Current methods for the detection of acaricide resistance take 6 to 15 weeks. Resistant ticks remain uncontrolled and may be dispersed during this period. The existing tests are not readily applicable to some new acaricides (c.g. growth regulators and systemics). We have examined alternative methods for the detection of resistant ticks using DNA technology with the aim of developing more rapid tests suitable for all classes of acaricide. The arbitrary primed polymerase chain reaction (AP-PCR) was used to analyse DNA from resistant and susceptible strains. The results demonstrated that the DNA fragments generated were similar for all strains tested when 20 different primer pairs were used. Using a different approach, we have now cloned and sequenced several tick microsatellite loci. Some loci contain extensive adjoining dinucleotide repeats of various types. PCR amplification of these loci from different tick strains is currently under evaluation as a means of generating strain-specific DNA fingerprints. It is possible that DNA fingerprinting could be used for the identification of resistant *B. microplus* strains and their origin worldwide.

RELAY TRANSMISSION OF MALARIA IN MALI.

D.Sangaré, S.F Traoré, A.Dao, M.Bouaré, G.Dolo,

M.Bagayogo, N.Sogoba, O.Niaré, K.Kayentao,

M.Diallo, O.Doumbo, R.Sakai and Y.T.Touré.

MRTC/DEAP. Ecole Nationale de Médecine et de Pharmacie, Bamako, Mali.

In the village of Donéguebougou a longitudinal entomological study was conducted from June 1994 to May 1995 to assess the malaria transmission pattern. The vectors were collected by spray and landing catches and identified by morphology, chromosomal and/or PCR methods. The infection rates were determined by ELISA. The malaria vector population was composed of 63% of *An.gambiae s.s.*, 26.4% of *An.arabiensis* and 10.6% of *An.funestus*. *An.gambiae s.s.* predominated during the rainy (June-October), *An.funestus* in the dry cool (Dec-Feb) and *An.arabiensis* in the dry hot (March-May) season. The infection rates were 5.4% for *An.gambiae s.s.*, 7.7% for *An.arabiensis* and 6.0% for *An.funestus*. Total annual entomological inoculation rate (EIR) was 32.5: 19.2 for *An.gambiae s.s.*, 10.4 for *An.arabiensis* and 2.9 for *An.funestus*.

Within *An.gambiae s.s.* the three chromosomal forms found were 16.1% Bamako, 20.6% Savanna and 56% Mopti and 7.3% others. Bamako and Savanna were seen only during the rainy season while Mopti persisted throughout the year. The total annual EIR for *An.gambiae s.s.* was partitioned as follows: 19.6% Bamako, 25.9% Savanna, 35.4% Mopti and 19.0% others. Transmission occurred throughout the year in close association with the population dynamics of the vector species and the chromosomal forms of *An.gambiae* in a relay pattern as species and chromosomal forms sequentially predominated at different times of the year.

23-061

MOLECULAR EVOLUTION AND SPECIATION IN *PHLEBOTOMUS PAPATASI* AND *LUTZOMYIA WHITMANI* (DIPTERA: PSYCHODIDAE) IN RELATION TO PERIDOMESTIC TRANSMISSION OF *LEISHMANIA*Paul Ready, John Day, Selma Esseghir¹, Jennifer Sackin, Riadh Ben-Ismaïl¹, Clive Davies²

Molecular Systematics Laboratory, Department of Entomology, The Natural History Museum, London, U.K.

¹L.E.E.P., Institut Pasteur de Tunis, Tunis, Tunisia²Department of Medical Parasitology, London School of Hygiene & Tropical Medicine, London, U.K.

We have assessed the relationships among geographical populations of two phlebotomine sandfly species by comparative analysis of mitochondrial and nuclear DNA sequences. *Phlebotomus (Phlebotomus) papatasi* (Scopoli, 1786) has a wide geographical distribution, from the western Mediterranean Basin to the Indian subcontinent. Peridomestic populations are found throughout this species' range but transmission of *Leishmania major*, although widespread, is limited to regions occupied by the parasite's reservoir hosts, which are usually gerbillid rodents. For *P. papatasi*, we have tested the hypothesis that peridomestic populations do not represent one or more sibling species distinct from populations associated with gerbil colonies.

In contrast, the neotropical phlebotomine we are investigating exhibits marked geographical differences in vectorial roles. *Lutzomyia (Nyssomyia) whitmani* (Antunes & Coutinho, 1939) is an incriminated vector of *Leishmania braziliensis* in North East and South East Brasil, where it is synanthropic, but of *Leishmania shawi* in Amazonia. In this case, we are testing the hypothesis that the Amazonian populations represent a distinct phylogenetic and biological species which is not abundant peridomestically.

This work is supported by project grants from the CEC/EU (Brussels) and The Wellcome Trust (London).

23-063

DISCRIMINATION BETWEEN *ANOPHELES GAMBIAE* S.S. CHROMOSOMAL FORMS BY PCR-RFLP ANALYSISG Favia, C.Fanello, Y T Touré¹, N Sagnon², M Coluzzi, A della Torre

Istituto di Parassitologia, Fondazione Pasteur-Cenci Bolognetti, Università "La Sapienza", Roma, Italy; ¹Ecole Nationale de Médecine et de Pharmacie, Bamako, Mali; ²Centre National de Lutte contre le Paludisme, Ouagadougou, Burkina Faso.

The polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP) approach has been used to discriminate between two chromosomal forms of *Anopheles gambiae* sensu stricto, the major malaria vector in Africa. These forms, namely Savanna and Mopti, are morphologically indistinguishable, but characterized by specific inversion polymorphisms. A ribosomal DNA fragment of 1.3 kilobase, that contains part of the Intergenic Spacer (IGS), has been PCR-amplified from genomic DNA extracted from pools of individuals belonging to either a Savanna or a Mopti laboratory colony. The fragment obtained was cut with several restriction enzymes, two of which (Tru9I and HhaI) yielded specific patterns for each colony. Carnoy's preserved field-collected, sympatric specimens of Mopti and Savanna from different localities in Mali and Burkina Faso were karyotyped and then analyzed by the above procedure: they were shown to correspond to the expected pattern. Therefore the PCR-RFLP technique may be applied for a unambiguous identification of the two *An.gambiae* forms and used to analyze large field-collected samples with no constraints due to life stages, sex or storing conditions. The analysis of the sequences of the PCR fragments is in progress in order to design specific diagnostic primers to be used to eliminate the restriction step from the procedure.

23-064

INTER SPECIES COMPARISONS OF REPETITIVE DNA COPY AND SEQUENCE VARIATION IN MEMBERS OF THE *ANOPHELES CULICIFACIES* COMPLEX

C.A. Malcolm, I.A. Shahjehan², R.J. Brown, Hema Joshi¹, K. Raghavendra¹ and Sarala K. Subbarao¹

School of Biological Sciences, Queen Mary and Westfield College, University of London, UK.

² Malaria Research Centre, ICMR, Delhi, India

Members of the *Anopheles culicifacies* complex are the major vectors of malaria on the Indian sub-continent. Four sibling species have been identified which can only be distinguished by analysis of ovarian nurse cell polytene chromosomes. In contrast to several other mosquito species complexes, the development of an alternative method for species identification based on DNA probes has proved difficult. Our studies using the standard approach, involving differential screening of small genomic DNA libraries have identified a number of DNA fragments which represent moderate to highly repetitive sequences. These fragments show differences in the degree of hybridisation to DNA from member species, but none were species specific.

A closer examination of the isolated DNA clones and homologous regions within the different species was made in the hope of fine tuning the species specificity. Details of five clones will be presented four from species B (B113, Ac9, Ac10, and Ac11) and one from species C (Ac3). Clone Ac11 contains an almost complete ribosomal RNA gene repeat unit, which has been fully mapped. Clone B113 contains a ~600 bp subfragment, adjacent to non-repetitive DNA. The sub-fragment has little or no internal repetition and appears to be a dispersed repeat. The remaining three clones contain fragments of satellite DNA sequences and are composed of tandem repeats.

23-065

VARIATION IN rDNA, mtDNA AND RAPD IN THE *ANOPHELES CULICIFACIES* COMPLEX (DIPTERA: CULICIDAE)

H. Townson, T. Adeniran, M. Oshagi, and N. Djadid

Division of Parasite and Vector Biology, Liverpool School of Tropical Medicine, Pembroke Place, Liverpool L3 5QA, UK.

Anopheles culicifacies is known to be a species complex that includes the most important malaria vectors in the Middle East and Indian sub-continent. Based on sequence differences in the second internal transcribed spacer (ITS2) of the ribosomal DNA (rDNA), we have developed a diagnostic Polymerase Chain Reaction (PCR) assay which readily distinguishes species A and B over an extensive part of their geographical range.

Significant sequence differences between these species have also been found in the mitochondrial DNA (mtDNA) cytochrome oxidase I-II genes, as well as some sequence variation between different populations within species. Species-specific mtDNA haplotypes may be distinguished both by sequencing and by restriction mapping.

Species-specific differences in the complex can also be demonstrated using random amplified polymorphic DNA (RAPD) PCR. In addition, some RAPD primers show variation between individuals from different geographic localities. Species-specific fingerprints are obtained using a novel technique involving PCR primers which carry 3'-anchored dinucleotide repeats.

We discuss the significance of our findings for understanding of the *An. culicifacies* complex and its role in malaria transmission. We also highlight some of the needs for future research.

23-066

BIOLOGY AND BEHAVIOR OF FORENSICALLY IMPORTANT FLIES

B. Greenberg, Department of Biological Sciences, University of Illinois at Chicago, Chicago, Illinois U.S.A.

BBC Natural History has released a forensic biology film called "Creatures in Crime" or "The Witness Was a Fly." We present the entomological portions with footage, often dramatic, of the biology and life cycles of some forensically important flies, including *Chrysomya rufifacies*, *Cochliomyia macellaria*, *Phormia regina*, and *Piophilidae casei*. One sequence shows the catapulting behavior of postfeeding larvae of *P. casei*, captured possibly for the first time by high speed camera. Another shows the predatory behavior of third instar larvae of *C. rufifacies*. Homicide cases are presented including those of Dr. Zakariah Ercinçlioglu of Cambridge University.

23-067

EFFECTS OF BURIAL ON RATE OF DECOMPOSITION, TEMPERATURE, AND INSECT SUCCESSION ON CARRION IN TWO BIOGEOCLIMATIC ZONES IN BRITISH COLUMBIA, AND THE IMPLICATIONS FOR FORENSIC ENTOMOLOGY.

VanLaerhoven, S.L. and Anderson, G.S.

Centre for Pest Management, Dept. Biological Sciences, Simon Fraser University, Burnaby, British Columbia, Canada

The time of carrion colonization by insects can be used to accurately determine time of death in homicide victims. However, there is very little knowledge on insect succession on buried carcasses, despite the fact that many homicide victims are buried. Until this work, no data on buried carcasses were available in Canada. Pig carcasses as human models were buried in Interior and Lower Mainland British Columbia, and were exhumed at regular intervals over a one year period and compared with above ground carcasses. Results of the effect of burial on insect colonization, rate of decomposition and carcass temperature, will be presented and the implications for minimum post mortem interval determinations will be discussed.

23-068

EXTRACTION, AMPLIFICATION, AND SEQUENCING OF HUMAN MITOCHONDRIAL DNA FROM INSECTS OF FORENSIC IMPORTANCE

W. D. LORD, J.A. DIZINNO, M.R. WILSON, B. BUDOWLE
Forensic Science Research and Training Center, Laboratory
Division, FBI Academy, Quantico, Virginia, U.S.A.

The ability to identify individual human hosts based on analyses of blood recovered from the digestive tract of hematophagous arthropods has been a long term pursuit in both medical and forensic entomology. Bloodmeal individualization techniques can bring important advancements to studies of vector-borne disease epidemiology. Forensically, these analyses may aid in assailant identification in violent crime cases where blood-feeding insects or their excreta are recovered from victims or at crime scenes. Herein, we report the successful isolation, amplification, and sequencing of human mitochondrial DNA obtained from adult human crab lice fed on human volunteers. Adult lice were removed from recruited volunteers frequenting inner city health clinics. Live lice were killed by freezing and subsequently air dried at ambient temperature. A reference saliva sample was obtained from each volunteer and served as a DNA comparison standard. Volunteers were afforded free, approved pediculosis treatment. Individual lice were subsequently processed using procedures developed for the extraction of mitochondrial DNA from human hair and bone. The resulting DNA was amplified by the polymerase chain reaction and sequenced by automation. While preliminary in nature, our results point to valuable avenues for future entomological research.

23-070

FORENSIC ENTOMOTOXICOLOGY - AN UPDATE.

F. Introna jr.

Institute of Forensic Medicine - University of Bari - ITALY.

Until some years ago diptera larvae were used in forensic science only to provide useful information on Postmortem Interval, on previous location of the corpse or its geographic origin. Entomotoxicology is a relatively new branch in forensic entomology due to the unbelievable increase in drug-related deaths all over the world. Recent studies have revealed that Diptera larvae can be used as toxicological specimens when no other cadaveric substances are available. So the analysis of Diptera larvae grown on a corpse can give useful indications regarding previous intoxication of the body (phenobarbital, triazolam, oxazepam, levomepromazine, cocaine, heroin, etc.). A toxicological cause of death can be now revealed even in the absence of the body just analyzing the larvae fed on it. Furthermore most of the chemicals can influence the life-cycle of maggots; recent studies concerning the effects of drugs and toxins on the rate of larval development have confirmed the opportunity of using larvae recovered from a corpse for PMI.

23-069

COPING WITH THE INHERENT VARIABILITY IN CARRION INSECT GROWTH AND SUCCESSION: STATISTICAL TECHNIQUES FOR ENTOMOLOGICALLY-BASED ESTIMATION OF THE POSTMORTEM INTERVAL

J.D. Wells, L.R. LaMotte¹

Department of Medical Entomology, National Institute of Health, Shinjuku-ku, Tokyo, Japan - 1 Department of Experimental Statistics, Louisiana State University, Baton Rouge, LA USA

We are developing techniques for calculating the statistical uncertainty in estimation of the postmortem interval (PMI). For PMI estimations based upon the length or weight of a larva from the victim, we suggest a computationally intensive but relatively straightforward method for calculating the regression line and a confidence interval about the estimated larval age. For PMI estimations based upon the stage of succession, we have expanded the occurrence matrix approach of Schoenly *et al.* for use with replicated data. A probability distribution for all possible sample combinations (each taxon or stage either present or absent) for each day of succession is empirically estimated. An adaptation of Fisher's exact test is then used to calculate a p-value for observing a particular sample at a given point of time in succession. The result is an interval of likely PMI values for a given death scene sample.

23-071

STATE OF OKLAHOMA v. HOWELL (PART I): THE USE AND VALUE OF ENTOMOLOGICAL EVIDENCE DURING THE MURDER INVESTIGATION AND SUBSEQUENT PRE-TRIAL IN OKLAHOMA

N.H. Haskell, R.D. Hall¹, B. Barnett², F. Muret³

Department of Biology, St. Joseph's College, Rensselaer, IN USA; 1- Department of Entomology, University of Missouri, Columbia, MO USA; 2 - Lincoln County Oklahoma District Attorney, OK USA; 3 - Attorney at Law, Stillwater, OK USA.

A bloated decomposing corpse of a human male was found under a pile of household items (comforter, dresser drawers, television set, cardboard and paper) beside a residential driveway in Stroud, Oklahoma, in the late afternoon on August 8, 1994. The last time the victim had been seen, he and his wife were leaving a nightclub at about midnight on August 4 and were engaged in a bitter argument. When questioned, the wife claimed that she had last seen her husband during the late evening of August 6, when he left with one of her friends.

Entomological evidence was collected from the remains at the scene and at autopsy. Two species of Calliphoridae were present as larvae. The oldest immatures were late, non-migrating 3rd instars *Cochliomyia macellaria* (F.); also present were early 3rd instar *Phormia regina* (Meigen). Under the climatic conditions prevailing during the period in question (highs about 30°C) and the exposure of the remains to direct solar radiation (no shading until late afternoon), it was estimated that in this case, oviposition of the fly eggs producing the larvae collected must have occurred no later than mid-morning on August 5. The prosecutor's insect evidence thus appeared to refute the wife's alibi. The defendant was charged with first-degree murder and the case was scheduled for trial, whereupon the defense requested a hearing regarding admissibility of the entomological evidence. When the evidence was ruled admissible, defendant sought a plea agreement and accepted the 25-year sentence offered by the prosecution. The importance of the insect evidence in this case is underscored by the fact that a lengthy and expensive trial was avoided.

23-072

STATE OF OKLAHOMA V. HOWELL (PART II): PROCEDURAL AND OTHER ISSUES IN RELATION TO ADMISSIBILITY AND WEIGHT OF ENTOMOLOGICAL EVIDENCE IN A MURDER TRIAL.

R. D. Hall¹, N. H. Haskell¹, F. Muret² and B. Barnett³

Department of Entomology, University of Missouri, Columbia, MO USA - 1
Department of Biology, St. Joseph's College, Rensselaer, IN USA - 2 Attorney
at Law, Stillwater, OK USA - 3 District Attorney, Lincoln County, OK USA.

To affect the result at trial in U.S. state and federal jurisdictions, scientific evidence, including entomology, must be admitted by the court. Motions to exclude may be made before or during trial and if successful, the evidence will not be considered. Common theories under which such exclusionary motions are made include logical and legal relevance, or competency of the evidence based either on privilege or on trustworthiness. The abovestyled case occurred in 1994 before Oklahoma adopted the admissibility standards articulated in *Daubert v. Merrell Dow Pharmaceuticals, Inc.*, 113 S.Ct. 2786 (1993), but was tried after such were adopted in *Taylor v. Oklahoma*, 889 P.2d 319 (1995). The defense introduced a pretrial motion to exclude that raised the issue of admissibility under 12 Okla. St. § 2702 (Oklahoma's codification of Federal Rule of Evidence 702) and requested a preliminary hearing under the *Frye* "generally accepted science" standard. The court applied *Daubert* and ruled the evidence admissible. The defense at this point had both consulting and testifying experts and continued matching the facts of the case with those strategies that might affect the weight of the scientific evidence in the prospective jury's evaluation. Although defendant pled guilty to a lesser charge before the case went to trial, *Oklahoma v. Howell* affords opportunity to evaluate the adversarial tactics that are commonly employed in defending against scientific testimony. Here, there were both strong and weak aspects to the prosecution's entomological case and the defense was prepared to exploit each of these on the merits before impeaching the prosecution's expert. The discussion will focus on the potential impact of the *Daubert* ruling on entomological testimony in light of the Federal Rules of Evidence, state codifications thereof, and the ambiguities inherent in determination of what constitutes "good science." Additional points include those entomological aspects in controversy in the instant case and how they could be attacked in the contexts of both court-appointed and adversarial expert witnesses.

23-074

PATTERN OF MYIASIS IN HUMAN CADAVER AND THE ESTIMATION TIME OF DEATH.

J. Surin, K. Ramakrishnan, R. Mahmud

Department of Parasitology, Faculty of Medicine,
University of Malaya, Kuala Lumpur, Malaysia.

A total of over 20 cases of myiasis found in exposed corpses for forensic investigations have been sent to and recorded in the Department of Parasitology. In all of these cases early stages of maggots were allowed to develop into adult stage in the laboratory and both were later identified. The dipterans involved are *Chrysomya megacephala*, *C. rufifacies*, *Sarcophaga*, *Hermetia illucens* and *Synthesiomyia nudiseta*.

The estimation of time of deaths for these forensic cases could be derived from the species and stage of dipterans found *in situ*.

In most cases the corpses attract primary and secondary invaders. The ages of the larvae and species of arthropods attacking the corpses can help forensic experts to determine the time of death, provided the detailed life cycle and history of the dipterans are known.

23-073

THE USE OF CARRION AS BREEDING SITES BY THE SHEEP BLOWFLY *LUCILIA SERICATA* AND OTHER CALLIPHORIDAE.

R. WALL & K.E. SMITH

School of Biological Sciences, The University of Bristol, Bristol,
BS8 1UG, U.K.

The use of vertebrate carcasses as breeding sites by larval Diptera was examined on two farms in South West England. *Calliphora vicina* was the dominant species to emerge; 19,294 individuals emerged from 175 of the 241 infested carcasses recovered. *Lucilia sericata* emerged from only 39 of the infested carcasses, at a median of ten adults per infested carcass. Other species of *Lucilia* present were *Lucilia ampullacea*, *Lucilia caesar* and *Lucilia illustris*. The highest number of *L. sericata* emerged from carcasses placed in open pasture, the highest number of *C. vicina* emerged from carcasses in hedgerow, while the highest numbers of *L. caesar*, *L. ampullacea* and *L. illustris* emerged from carcasses in woodland. The duration of exposure of carcasses in the field was negatively related to the size of the adult *L. sericata* which emerged and, in the woodland and hedgerow habitats, to the number of *L. sericata* which emerged. These data indicate that the larvae of *L. sericata* in carcasses experience significant levels of competition and that the intensity of this competition may be sufficient to reduce the number of *L. sericata* that are able to emerge from carrion. The results are discussed in relation to the development of novel methods of control of blowfly strike of sheep.

23-075

THE DEVELOPMENT OF LARVAE OF *CALLIPHORA ERYTHROCEPHALA* IN A BODY BURIED IN THE SNOW

V. Querci[°], M. Gabbrielli ^{*}, G. Mandriani[^]

[°] Dipartimento di Scienze Medico-Legali - Università di Siena

^{*} Istituto di Medicina Legale - Università "La Sapienza" Roma

[^] U.O. Medicina Legale - U.S.L. 7 Siena

The development of fly larvae exposed to low temperatures has been a subject of interest for some time, also due to the practical implications which derive from it. Unfortunately it has not yet been possible to obtain results of any absolute certainty and, for this reason, this case seemed to us worthy of note. It is the case of the discovery of *calliphora erythrocephala* in a body of the female sex, found in the open countryside after the thawing of a heavy snowfall which had lain for more than 15 days in the month of January, with low night temperatures but with good exposure to the sun during the day. The reexamination of the data contained in literature together with the experimental studies allowed the time of death to be established before the snowfall, a finding which was also in agreement with the circumstantial data.

In fact, it was possible to establish that the laying of the eggs had taken place before the snowfall and the larvae had developed despite adverse environmental conditions.

23-076

EXTERNAL TEMPERATURE AND BODY TEMPERATURE IN LARVAL INFESTATION, A RELATIONSHIP.

F. Introna jr., C.P. Campobasso, A. Di Fazio

Institute of Forensic Medicine - University of Bari - ITALY.

In forensic cases maximum and minimum temperature at the crime scene is recorded for entomological investigations. Temperature is indeed the most important variable for the rate of growth of fly larvae found in a corpse. Previous studies have discussed the effect of microclimatic conditions on larval development. An increase of internal temperature of a corpse during the advanced stages of larval infestation has been supposed; this over-heat has been related with the metabolic effect of larvae feeding clusters on the body. Anyway no relationship has been described between temperature at which the body was exposed and internal temperature in case of larval infestation. In such a case, time of death determination by internal body temperature can be underestimated. We have then performed an experimental investigation on animal corpse (rabbit) to study the autonomous capability of the larval cluster to increase the internal temperature of a corpse. Data concerning environmental microclimatic conditions (max. and min. temperature, humidity) at the body exposure place and inside body temperature in cluster feeding site were recorded daily. The results revealed a different increase of internal body temperature in cluster feeding site related with the larval developmental rate, the site of the cluster and the external microclimatic conditions.

23-078

THE USE OF DIPTEROUS MAGGOTS AS TOXICOLOGICAL INDICATORS IN FORENSIC ENTOMOLOGY

J.M.C. van Wyk¹, T.C. van die Linde¹ & H.K.L. Hundt²

Departments of Zoology & Entomology¹ and Pharmacology², University of the Orange Free State, P.O. Box 339, Bloemfontein 9300, South Africa

Forensic Entomology is a relatively new research field in South Africa. Estimating the post mortem interval (PMI) is probably the most important aspect of the Forensic Entomologist's task. Although the development stage of the insect larvae (dipterous maggots) on the corpse may be influenced by environmental conditions, drugs or poisons in the corpse may also effect its development and thus have an influence on the estimation of the PMI. In South Africa there is an escalating misuse of clozapine in combination with alcohol to incapacitate victims before robbery. Although many of the victims are brought to hospital for treatment, the number of victims which die as a result of the assault is increasing. Very often the bodies are found several days after death, at a stage when the usual toxicological determinations are complicated by decomposed tissue. This prompted us to establish whether dipterous maggots can be used as toxicological indicators in forensic entomology case studies.

A headspace GLC procedure was developed for the assay of ethanol in the maggots and in the stomach contents, muscle and liver tissue of decomposing rabbit carcasses. Using 20 mg tissue (or maggots) per headspace vial, the assay is sensitive enough to determine ethanol at 0,4 µg contained per headspace vial which converts to 20 mg/100 g tissue (or maggots). After 17 days, when the last maggots left the rabbit carcass, ethanol could still be detected in the maggots.

The assays on the combination of ethanol and clozapine is still in progress.

23-077

THE DETECTION OF DRUGS IN INSECTS AS ALTERNATIVE TOXICOLOGICAL SPECIMENS FOR FORENSICS

M.L. Miller, W.D. Lord, M.L. Goff ¹

Forensic Science Research and Training Center, Laboratory Division, FBI Academy, Quantico, Virginia, U.S.A. - 1 University of Hawaii at Manoa, Honolulu, Hawaii, U.S.A.

The forensic importance of insects and their remnants has been well established in the determination of time of death, and has recently been recognized as an alternative toxicological resource. The development of methods of analysis for toxins and controlled substances in insects can make an important contribution to the assessment of cause/manner of death in cases of advanced decomposition. Toxicological samples are often absent when mummified/skeletalized remains are found and entomological samples may provide the only clues. Applicable methods have been developed for drugs in beetle exuviae, fly larvae and puparia. Anti-depressants and stimulants in insects have been quantified using hyphenated techniques of chromatography and mass spectrometry. These methods have been utilized in actual forensic casework and provided complementary information. In addition, controlled laboratory animal studies are being conducted to examine the transfer and pharmacology of drugs from donor subjects (rabbit liver) to carrion insects. These experiments demonstrate that amounts found in insects are related to the dose and time of death after administration of the drug. Both parent and metabolite drugs can often be found in the insect tissues.

23-079

OPIATE ANALYSIS ON EMPTY PUPARIA - POSITIVE RESULTS

F. Introna jr., R. Gagliano Candela, G. Di Vella

Institute of Forensic Medicine - University of Bari - Italy

The contribute of entomological evidence in forensic cases is already known for evaluating the time and geographical location of the body. Fly larvae, reared on a known toxicological substrate, have been also tested for drug qualitative analysis. So it has been proved that cadaveric fly larvae can be used as laboratory specimens when no other cadaveric remains are available. Anyway this is a very rare case in criminal investigation. More easy to find in the daily forensic routine skeletonized remains with empty puparia. In these cases toxicological analysis can be performed only on bone fragment. We have than set up an experimental research to reveal if toxicological analysis can be performed with success on empty puparia. Empty cases of *Calliphora Erythrocephala* obtained by 20 experimental liver rearings with known different morphine concentration. Opiate quantitative and qualitative analysis was then performed using Fluorescence Polarization ImmunoAssay (FPIA). The results revealed an opiate positive qualitative analysis for empty cases obtained by the specimens with the highest morphine concentration used (10 mcg/g tissue). This evidence allowed to use in extreme forensic cases even the empty puparia of cadaveric blowflies as useful specimens for toxicological analysis. A new field in forensic entomotoxicological is opened. In the future when all the toxicological research will be performed, a complete drug screen will be allowed even in historical cases just using as toxicological specimen the empty cases of cadaveric flies.

23-080

FORENSIC ENTOMOLOGY ACTIVITY IN SOUTHERN ITALY: AN ENTOMOLOGICAL STUDY ON ANIMAL CORPSES.

F. Introna jr., C.P. Campobasso, A. Di Fazio.

Institute of Forensic Medicine - University of Bari - ITALY.

In forensic entomology any accurate determination of Postmortem Interval by arthropod succession should be done using species related with the place where the body was found. The goal of this research is to provide a more reliable method for PMI estimation based on entomological evidence and seasonal factors revealed all over the year in Southern Italy. For this purpose we have performed an experimental investigation on the insect fauna of decaying corpse carried out on animal carrion (rabbits) placed at intervals of about two weeks in open field in a suburban habitat. We have intentionally limited our researches to the study of cadaveric flies of the first wave for a better definition of the time since death in the earliest stages of decomposition. Data concerning climatic conditions, body decomposition and insect activity have been recorded daily. Entomological specimens from corpse and from surrounding area before and after removal of the remains have been collected. We have indeed analyzed the time necessary for egg deposition, egg hatching, larvae development and pupation of blowflies based on different parameters such as degree of decay and seasonal weather (lighting, temperature, humidity, rainfall).

23-081

HANGING OUT AT THE SIXTEENTH HOLE AND JACK'S IN THE BOX

M. Lee Goff

Department of Entomology, University of Hawaii at Manoa, Honolulu, Hawaii 96822, USA.

Patterns of invasion of remains by arthropods and resulting patterns of decomposition may be altered by the circumstances of the body. Two examples of unusual disposals of remains are presented here with comments on the changes in the resulting patterns of arthropod invasion.

In the first instance, the body was found hanging in a wooded area of the Ala Wai Golf Course in Honolulu. In this case, the initial invasion was by arthropods which could fly onto the body. Access by soil dwelling arthropods was delayed until the body stretched enough for the feet to reach the ground. There were significantly fewer taxa involved in this decomposition when compared to remains exposed on the ground surface. A secondary site of arthropod activity was noted in the drip zone under the suspended body.

In the second instance, the body had been dismembered and placed inside a metal tool box. When discovered, there were few arthropod taxa represented by living forms or puparial cases. The postmortem interval was established by analyses of the activities of the Stratiomyidae *Hemelia illucens* and the period required for a colony of ants to produce reproductive forms.

23-082

INTRODUCTION TO THE CONCEPT OF REPLACEMENT OF A VECTOR POPULATION BY A HARMLESS GENOTYPE

C.F. Curtis

London School of Hygiene and Tropical Medicine, Keppel Street, London, WC1E 7HT, UK

Members of an insect species which is normally a vector of human disease could be rendered harmless by a gene or genes which caused either (i) interference with development of the parasite (refractoriness) or (ii) biting of animals (zoophily) and not humans.

For efficient spread in a wild population it is desirable that a single gene (not polygenes) is involved and that it is dominant and does not cause serious loss of fitness. Two or more independent forms of refractoriness would make it less likely that the parasites could evolve evasion mechanisms.

A suitable genetic driving system could (i) spread the genes from a small "seeding", and (ii) counter the effects of immigration from surrounding vector populations. These are potential advantages of making populations genetically harmless as compared to attempted eradication by the mass release of sterile males.

IDENTIFICATION OF GENES THAT CONFER PLASMODIUM-REFRACTORINESS IN ANOPHELES GAMBIAE

Frank H. Collins, Division of Parasitic Diseases, Centers for Disease Control and Prevention, Atlanta, GA, 30333, USA

One approach to the identification of genes that could reduce or block the ability of the mosquito *Anopheles gambiae* to transmit malarial parasites has been to genetically select strains of this mosquito that are refractory to the parasite and then use molecular approaches to identify the responsible genes.

Two forms of refractoriness which seem to be regulated by only one or a few genes have been identified by this approach. In one form of refractoriness, the ookinete is encapsulated shortly after it completes its passage through the midgut epithelium. In the other form, the parasite is killed by lysis as it passes through the midgut cells. A strategy for positional cloning of these encapsulation and lytic factor genes is now being implemented. This strategy combines high resolution genetic mapping with microsatellite loci and chromosome walking with a large fragment genomic library in a bacterial artificial chromosome (BAC) vector. Ultimately, candidate genes identified by this strategy will be verified by germ line transformation. Progress in the development of these tools and their use in cloning malarial parasite refractoriness genes will be described.

23-084

THE INTRODUCTION OF GENES CODING FOR TRANSMISSION BLOCKING ANTIBODIES INTO THE GENOME OF *ANOPHELES GAMBIAE*: A PROGRESS REPORT

J.M. Crampton¹, F. Spano¹, F. Nardone¹, G.J. Lycett, H-M. Muller¹, R.E. Sinden², A. Crisanti^{1,2}

Liverpool School of Tropical Medicine, Pembroke Place, Liverpool, L3 5QA, UK - 1 Istituto di Parassitologia, Università degli Studi di Roma, La Sapienza, 00185 Roma 1, Italy - 2 Department of Biology, Imperial College of Science, Technology and Medicine, London SW7 2BB, UK.

Insect vector control has proved an effective method for reducing the transmission of disease-causing organisms to human populations in many tropical countries. However, the development of insecticide resistance by vector insects, the cost of developing and registering new insecticidal compounds, and the increase in legislation to combat the detrimental effects of insecticidal residues on the environment, have emphasised the need to assess a variety of alternatives to vector control. We are interested in employing direct genetic manipulation of insect vector genomes either to suppress vector populations, or to alter their ability to transmit disease-causing organisms in such a way as to have a profound and long-lasting effect on disease transmission. The particular focus of our research is to alter the ability of mosquitoes to act as vectors of malaria by introducing heterologous transmission modulating genes into the mosquito genome. In a series of model experiments in which we will assess this concept, we have introduced the genes necessary to produce transmission blocking antibodies in the mosquito midgut so that they are expressed when it takes an infected blood meal. Transmission blocking antibodies, based on the Pfs25 and Pbs21 antigens of *Plasmodium falciparum* and *P. berghei*, are well characterised molecules known to block transmission when present in an infected blood meal. The progress which has been made towards achieving this goal will be discussed, with particular emphasis on: a) the identification of endogenous transposable elements in mosquitoes which may be used as DNA vectors for the manipulation of mosquito genomes; b) the identification of putative gut-specific, blood-meal inducible promoters in mosquitoes which may be used as a transmission-blocking antibody expression cassette; c) the assessment of the activity of these promoters in mosquito tissues and cells.

WOLBACHIA INFECTIONS AS A GENERAL VEHICLE TO DRIVE REFRACTORINESS GENES INTO INSECT POPULATIONS

S. L. O'Neill, S. Sinkins

Department of Epidemiology & Public Health, Yale University, New Haven, CT USA

Wolbachia infections could potentially be used as vehicles to drive refractoriness genes into natural populations of insects. This could be accomplished in two ways depending on the mode of inheritance of the genes of interest. Natural *Wolbachia* infections would indirectly drive maternally inherited genes with them as they spread into a population through the action of cytoplasmic incompatibility. Experimental data shows that *Wolbachia* superinfections provide a method to repeatedly spread maternally inherited genes into the same host population.

Modeling shows that chromosomal genes could also be spread into an interbreeding population if the *Wolbachia* genes that induce cytoplasmic incompatibility could be isolated from *Wolbachia*, integrated onto insect chromosomes and expressed appropriately. As these genes spread they would be expected to drag with them linked genes of interest.

NATURAL POPULATION REPLACEMENT AND COMPETITIVE EXCLUSION IN THE *ANOPHELES GAMBIAE* COMPLEX

M. Coluzzi, Y.T. Touré¹, V. Petrarca

Istituto di Parassitologia, W.H.O. Collaborating Centre for Malaria Epidemiology, Università "La Sapienza", P.le A. Moro 5, 00185 Roma, Italy; ¹Ecole Nationale de Médecine et de Pharmacie, Bamako, Mali

The severity of the malaria problem in sub-Saharan Africa depends mainly on the exceptionally high vectorial capacity of the two most anthropophilic members of the *Anopheles gambiae* complex, namely *An. gambiae* and *An. arabiensis*. These mosquitoes represent the principal target for the development of new control strategies including vector population replacement whose feasibility needs to be evaluated. Within this context, some of the available biogeographical data are of particular interest since they suggest the natural occurrence of replacement and competitive exclusion. The most relevant case refers to the sub-Saharan belt of arid savannas, below the 800-mm isohyets, from Senegal to Sudan. *An. arabiensis* alone exploits this environment in Sudan, successfully colonizing the seasonal, rain dependent, larval breeding sites as well as those available during the dry season, mostly associated with irrigation (e.g., Gezira). *An. arabiensis* coexists westwards with the chromosomal form Savanna of *An. gambiae*, the former sibling being still generally dominant in most localities of Cameroon, Nigeria and Senegal. The picture changes completely in Mali and Burkina Faso where the irrigated areas show the unexpected dominance of *An. gambiae* represented by its chromosomal form Mopti, a very effective dry season breeder typical of rice cultivated zones. However, out of the Mopti range the same ecological areas are successfully colonized by *An. arabiensis* and, less intensively, by *An. gambiae* Savanna. Incidentally, *An. arabiensis* is well known as the dominant member of the complex also in rice cultivated areas of East Africa. We favour the hypothesis that, wherever dry season breeding opportunities exist in Mali and Burkina Faso, the most recent Mopti taxon replaced *An. arabiensis* and *An. gambiae* Savanna. These taxa occur only at the periphery of the Mopti colonized areas and the stability of such pattern of distribution during the rainy season suggests the existence of competitive exclusion.

**A SPATIAL MODEL FOR GENETICALLY MODIFYING
FLUCTUATING MOSQUITO POPULATIONS**

**Anthony E. Kiszewski Andrew Spielman
Harvard School of Public Health, Boston, MA, USA**

Our stochastic automaton model for genetically modifying anophelines in nature represents transposon release into a dispersed, clumped, seasonally fluctuating, locally mating population. Contrasting scenarios of population fluctuation are compared: one assuming that anopheline density remains constant; another assuming rigorous estivation and the last assuming seasonally reduced breeding density. Diverse fitness parameters and transposition efficiencies also are examined. As transposon fitness approaches 50%, fixation requires that insertion efficiency approaches unity. In a heterogeneous space and with fluctuating population density, however, fixation may require thousands of generations. When estivation is stringent, fitness must exceed 70% to achieve fixation. We conclude that the clumped, fluctuating characteristics of peridomestic anopheline populations resist fixation.

BIOLOGICAL CONTROL OF *CULEX QUINQUEFASCIATUS* BY MYCELIA AND METABOLITES OF *PAECILOMYCES LILACINUS*

S.P. Agarwala, S.S. Sehgal

Department of Zoology, University of Delhi, Delhi-7, India

Paecilomyces lilacinus, a microbial fungus, has been explored for the first time as biological control agent against mosquito, *Culex quinquefasciatus* in order to curtail the excessive use of chemical insecticides. The fourth instar larvae of the mosquito were exposed to 1.0% mycelial suspension of *P. lilacinus*. It caused about 70% larval mortality and 16% adult emergence. The third instar larvae of *C. quinquefasciatus* exposed to different concentrations of Czapeckdox metabolites of the fungus. The ill effects evaluated on growth, development and mortality were non-significant ($P > .05$). Similarly, PYG metabolites of the fungus used against the third instar larvae of *C. quinquefasciatus* had a significant ($P < .01$) effect on the growth and mortality. The results indicate that the fungal mycelia can be a good bio-control agent against *Culex* mosquito. In Czapeckdox medium no toxic metabolite is produced, hence has no use in mosquito control but PYG metabolite appears to be a promising bio-control agent.

23-090

UTILISATION OF SPORE-PREPARATION AND METABOLITES OF A FUNGUS, *BEAUVERIA BASSIANA* IN BIOLOGICAL CONTROL OF *AEDES AEGYPTI*

S.S. Sehgal, S.P. Agarwala

Department of Zoology, University of Delhi, Delhi-7, India.

The first instar larvae of *Aedes aegypti* were exposed to spores of *Beauveria bassiana* suspended in distilled water at a concentration of 0.4×10^7 spores/ml. This resulted in 100% larval mortality in nine days. Escalated dose of 1.6×10^7 spores/ml, however proved fatal in seven days. The aged larvae appeared more susceptible. The later dose killed all the third instar larvae in three days.

The fungal metabolites in Gelatin medium caused a significant mortality at a high concentration (25%) and reduced the survival time from 9.85 days in control to 2 days. Strangely the low dosages (3%) and below stimulated the growth resulting in high growth index of the larvae. On the other hand metamobites in PYG medium did not induce any stimulating effects. Metabolites in Czapeckdox medium accelerated the egg laying rate which was most pronounced at 6.25% concentration. Increased concentrations however, showed a dose-dependent reversal of this effect.

The metabolites were found to be thermolabile.

23-091

EFFECTS OF ACETONE EXTRACT OF NEEM (*AZADIRACHTA INDICA* A. JUSS) SEED COAT AGAINST *AEDES AEGYPTI* AND *CULEX QUINQUEFASCIATUS* TREATED AS THE FIRST INSTAR LARVAE.

S.K. Sagar, S.S. Sehgal

Department of Zoology, University of Delhi, Delhi-7, India

Acetone extract of neem (*Azadirachta indica* A. Juss) seed coat (ACNSC) was used against *Aedes aegypti* and *Culex quinquefasciatus* to assess its toxicity, growth regulating capacity and impact on hatchability. When *Ae. aegypti* Larvae in their first instar were exposed to a low concentration (10 ppm) of ACNSC, no mortality was observed. The larval mortality occurred with increased doses in a dose-dependent manner. A concentration of 40 ppm caused 100% mortality of the first instar larvae. While in *Cx. quinquefasciatus* mortality of same magnitude was caused by a dose of 20 ppm. Even at lower concentration of 10 ppm, 13.3% pupal mortality was observed in *Cx. quinquefasciatus* but no pupal casualty occurred in *Ae. aegypti*. Insect growth effect of ACNSC assessed in both the species but in *Ae. aegypti* the effect was more pronounced and a severe effect was seen at the eclosion. ACNSC (50ppm to 250 ppm) was administered on eggs of both the species but no adverse effect on hatching was seen.

23-092

SEQUENCE DIFFERENCES IN THE MITOCHONDRIAL CYTOCHROME OXIDASE I-II GENES OF SPECIES A AND B OF *ANOPHELES CULICIFACIES*

M.A. Oshaghi and H. Townson

Parasite and Vector Biology Division, Liverpool School of Tropical Medicine, Pembroke Place, Liverpool, L3 5QA, UK.

Anopheles culicifacies is known to be a species complex comprising at least four species that include important malaria vectors in the Middle East and Indian sub-continent. Here we present evidence that two of the species, A and B, can be differentiated by their mitochondrial DNA haplotype.

DNA was prepared from individual field-collected specimens from Iran, Pakistan and Sri Lanka. Following polymerase chain reaction (PCR) amplification of a 1500bp segment of the cytochrome oxidase I and II genes, the amplification product was used for restriction mapping. Using seven restriction enzymes, 21 different restriction sites were found in the PCR product. Three enzymes, EcoRV, HinfI and AluI, gave a total of 14 sites of which 9 differed between two species.

A 766bp segment of the COI gene was sequenced. Nucleotide differences between the two species were observed at 46 positions, mostly T→C transitions (54.4%).

Although it remains to be confirmed that these mitochondrial haplotype differences are consistent throughout the species range, the evidence indicates substantial differences between COI-II genes of species A and B, at least as great as those seen between species of *Anopheles gambiae* complex (Oshaghi and Townson, unpublished observation).

COMBINED DEPRESSION OF FLIES QUANTITY AT FARMS AND URBAN OBJECTS USING CHEMOSTERILANTS, INSECTICIDES AND REGULATORS OF INSECTS DEVELOPMENT (RID)

M. Kostina

Laboratory of Arthropods Control System Development, Scientific Research Institute for Preventive Toxicology and Desinfection, Moscow, Russia

Methodics principles of sex chemical sterilization (food attractions with dimatif, thioTEF, hemf) were elaborated using natural flies populations. This method has high effectiveness (98,1-99,5%) and is the only way for the struggle with flies at the isolated territories: dry sugar food attractive at the aride zone and damp one at the temperate zone. Flies quantity reduction was registered in 2 weeks, clutch reduction (untill 41 eggs in a clutch) - in a month, the survival of progeny wasn't exceed 16% towards the end of 6th month (with corresponding control value 98%). The degree of nature flies populations sterility (at 10 large stock-breeding farms and 238 urban objects) wasn't exceed 41% owing to insufficient engage of attractions and flies getting from outside.

The employment of imagocides (carbophos, DDVF, ambush), larvicides (dimilin, alcistine, methopren) and adhesive glue compositions in addition to chemosterilants increased the effect till 99,2% during the periods of maximal flies quantity. Larvicides (JHA and CSI) ensured flies exclusion absence during 25-28 days. The combination "chemosterilant - feromone" (cis-9-trikozen, 1 mg per rubber dispenser, 10-20 traps per hectare) has high efficiency. Recommendations are developed for integral system of struggle with flies.

ERADICATION OF GLOSSINA AUSTENI ON UNGUJA ISLAND (ZANZIBAR) BY THE STERILE INSECT TECHNIQUE (SIT)

Dyck, V.A., Msangi, A.¹, Shambwana, I.A.², Malele, I.¹, Saleh, K.M.², Vreysen, M.J.B., Parker, A.G., Zhu, Z.-R. and Pan, H.J.

International Atomic Energy Agency, Vienna, Austria; 1 - Tsetse and Trypanosomiasis Research Institute, Tanga, Tanzania; 2 - Department of Livestock Development, Zanzibar, Tanzania

The one tsetse species present on Unguja Island, *Glossina austeni* Newstead, is responsible for the cyclical transmission of African animal trypanosomosis. Efforts between 1986 and 1993 substantially suppressed the *G. austeni* population by applying pour-on insecticides to cattle and deploying insecticide-treated screens but this did not result in eradication.

In order to achieve eradication, the SIT was integrated into these efforts. At Tanga, a colony of 400,000 flies is being maintained. Leaving the sexes together after mating at a ratio of 1 male to 5 females, improved rearing efficiency. The colony currently provides 40,000 sterile males for release weekly. Gamma-sterilized flies, packed in special paper boxes, are released twice a week through a chute in an aircraft. This permits even dispersal of sterile males, also over areas that are inaccessible from the ground. Two million sterile males were released by air within 16 months.

As of May 1995, the numbers of sterile males released were sufficient to exceed the desired ratio of 15 sterile to 1 wild male in the field. Fly densities are monitored with sticky blue/white panels. The impact of sterile male releases, as revealed by fly population monitorings, are: (i) exponentially increased levels of induced sterility in wild females, as shown by dissection of trapped females, and, consequently, (ii) a progressive decline in the wild fly population density. A collapse of the target tsetse population is anticipated by 1997 at the latest. To detect very low levels of fly activity, blood samples from sentinel herd cattle are monitored for the transmission of trypanosomosis. Parasitological and immunological tests are used. With the former method, no transmission was detected in a large part of the island during recent surveys.

THE USE OF SANITATION TO REDUCE STABLE FLY (DIPTERA: MUSCIDAE) POPULATIONS IN BEEF CATTLE FEEDLOTS

G.D. Thomas, S.R. Skoda¹, D.R. Berkebile¹, J.B. Campbell²

Midwest Livestock Insects Research Laboratory, Agricultural Research Service, United States Department of Agriculture, Lincoln, NB USA - 1 Midwest Livestock Insects Research Laboratory, Agricultural Research Service, United States Department of Agriculture, Lincoln, NB USA - 2 Department of Entomology, University of Nebraska, Lincoln, NB USA.

The stable fly causes \$400 million in losses to the United States cattle industry annually. Sanitation (waste management) has been long recommended as a means of reducing stable fly populations at cattle feedlots, but there is little published research to support the recommendation. Therefore, we conducted complete sanitation studies for two years in beef cattle feedlots in Nebraska. We found that this procedure reduced stable fly populations as much as 50%. In most cases this reduced the stable fly populations below the economic injury level.

23-096

DETECTION OF MOLECULAR VARIATION IN *AN. GAMBIAE* COMPLEX USING RAPD-PCR

N. D. Djadid & H. Townson

Liverpool School of Tropical Medicine, Pembroke Place, Liverpool, U.K.

Random amplified polymorphic DNA (RAPD)-PCR is a powerful tool for fingerprinting anonymous genomes. We have analyzed genomic DNA and developed RAPD-based diagnostic molecular markers for *An. gambiae* complex species from different part of Africa. After studying 54 arbitrary primers, we found three primers one ten-mer and two 17-mer that permitted differentiation of all six members of *An. gambiae* complex: *An. gambiae* s.s., *An. arabiensis*, *An. merus*, *An. melas*, *An. quadriannulatus*, and *An. bwambae*. However some primers from the OPA series showed extensive intra-specific variation within species of *An. gambiae* complex.

In terms of reproducibility of RAPD products, our results demonstrate that this technique is sensitive to the temperature profile, DNA concentration and extraction method, and the source of Taq polymerase. We found that 5 pg of Phenol extracted DNA produce more and sharper bands than higher concentrations. Taq polymerase from some sources gave bands in the negative controls (all reagents except template DNA) presumably because of contaminating bacterial DNA. A two step program with an annealing temperature of 36 and 50°C proved most suitable.

23-097

Studies of inter- and intra-specific genetic variation in malaria vectors using PCR primers targeted at random sequences and simple sequence repeats

N.D.Djadjid and H. Townson

Liverpool School of Tropical Medicine, Pembroke Place, Liverpool, UK

We have used RAPD-PCR (random amplified polymorphic DNA polymerase chain reaction) to differentiate field-collected specimens of species A and B of the *An. culicifacies* complex from the Middle East and Indian subcontinent. One RAPD 10-mer primer produced two fragments, a 630 bp band specific to species B and a 420 bp band common to both species. A 17-mer primer also differentiated species A and B but showed additional variation in Iranian samples from different collection sites. 'Fingerprints' characteristic of the two species were obtained following PCR with a primer carrying a 3' anchored dinucleotide repeat.

In *An. stephensi*, strain and sample-specific RAPD patterns were obtained for seven laboratory strains and field samples originating from the Middle East and India.

Specimens of *An. subpictus* from inland and coastal sites in Sri Lanka showed two distinct fingerprints following PCR with a 3' anchored dinucleotide repeat primer.

This study demonstrates the value of RAPD primers and those targeted at simple sequence repeats, not only in differentiating seemingly isomorphic species but also in defining genetic differences between populations within a species, both factors of importance in malaria epidemiology.

23-099

BIOEFFICACY OF HEXANE EXTRACT OF KARANJA (*PONGAMIA GLABRA* VENT) SEED KERNEL- AGAINST MOSQUITO.

S.S.Sehgal, S.K.Sagar

Department of Zoology, University of Delhi, Delhi-7, INDIA

Hexane extract of karanja, *Pongamia glabra* Vent (Fabaceae) seed kernel (HKSK) ranging at the concentrations of 4 ppm to 28 ppm was evaluated against the freshly emerged larvae of *Aedes aegypti* and *Culex quinquefasciatus*. Treatment of HKSK imparted the mortality that was correlated with the level of dosage. Before pupation, 100% fatality occurred in *Ae. aegypti* at a concentration of 20 ppm whereas in *Cx. quinquefasciatus* the same degree of mortality occurred at the extract concentration of 12 ppm in the first instar only. At low doses, the ensuing adults of *Cx. quinquefasciatus* had deformed legs, wings and truncated abdomen but the adults of *Ae. aegypti* showed no deformities. The developmental period was prolonged significantly in a dose-dependent manner for both the species treated. In *Cx. quinquefasciatus* this effect was more pronounced because of increased intermoult period showing an IGR effect of the extract. The calculated growth index also decreased in dose-dependent manner significantly more in *Cx. quinquefasciatus*. Indeed, *Ae. aegypti* appeared more vulnerable to HKSK than *Cx. quinquefasciatus*.

23-098

A DIAGNOSTIC TEST BASED ON SEQUENCE DIFFERENCES IN THE RIBOSOMAL DNA OF SPECIES A AND B OF THE *ANOPHELES CULICIFACIES* COMPLEX (DIPTERA: CULICIDAE).

H.Townson and T.Adeniran

Division of Parasite and Vector Biology, Liverpool School of Tropical Medicine, Pembroke Place, Liverpool L3 5QA

We have sequenced the second internal transcribed spacer (ITS2) of the ribosomal DNA (rDNA) of species A and B of the *Anopheles culicifacies* complex and identified a number of species-specific differences.

Based on these sequence differences, two primers were designed and tested in a Polymerase Chain Reaction (PCR) together with a conserved 5.8S primer and produced an amplification product of 250bp with target DNA from species A and one of 410bp with species B.

This PCR assay has given consistent and reproducible results with individual mosquitoes of field samples from Iran, Pakistan, India and Sri Lanka and correctly differentiates species A and B in the progeny of chromosomally-identified adults. Sequence data for the mitochondrial cytochrome oxidase I gene (Oshagi and Townson, unpublished observations) also readily differentiates these two species.

23-100

OVARIOLE BASAL BODY DEVELOPMENT AND PHYSIOLOGICAL AGE OF HAEMATOPHAGOUS DIPTERA

T. Q. Hoc, G. A. Schaub¹

Faculty of Biology, the State Hanoi University, Hanoi, Vietnam

¹Fakultät für Biologie, AG Spezielle Zoologie, Ruhr-Universität Bochum, Bochum, Germany

Females of several dipteran families (Culicidae, Simuliidae, Tabanidae) possess in each ovariole a group of six to nine specialized epithelial cells in a region of the calyx wall that is enclosed by the end of the ovariole sheath is termed the basal body.

In all ovarioles of nulliparous females, and in those ovarioles of parous females in which ovulation had apparently not occurred, the cells of the basal body did not appear granular. However, after the first mature oocyte had entered the calyx lumen through the basal body, granulation occurred. Such a basal body is designated as a granular basal body. The size and intensity of granular basal bodies increased after every subsequent oviposition.

The granular basal bodies differ from all previous described ovarian structures. They may have a role in recycling used materials including egg sac remnants after every oviposition.

Examination of the granular basal bodies in intact ovaries, supravitality stained with neutral red, provided an easy method for distinguishing parous from nulliparous females, and has potential as a new method of age grading.

Study of Leptoconops in China
Zengjia Liu

Institute of Military Medical Science of Lanzhou

Leptoconops are biting midges of Leptoconopinae, Ceratopogonidae. According to literature, Leptoconops in Neimenggu were reported by Okada early in 1954. Leptoconops (Holoconops) yunhsiensis in Hanshui River valley of Wudang Mountain, Hubei Province were collected by Yixin Yu in 1957. For the first time, a new species of Leptoconops was named by Chinese scholar in study history of Ceratopogonidae. New species of Leptoconops in Fujian, Yunnan and Tibet province were reported respectively by Keqin Sun and Tiesheng Li in 1968 and 1978. "Study of Leptoconops in Northwest China" were published by Zengjia Liu in 1990. For the first time, a monograph of Leptoconops were published by Chinese scholar in study history of Ceratopogonidae. Up to now, 34 species of Leptoconops respectively belonging to 3 Subleptoconops, were found: 28 species of Holoconops, 5 species of Leptoconops and 1 species of Acanthoconops. They are distributed in these areas: 15 species (44.12%) in Xingjiang, 2 species (5.88%) in Qinghai, 11 species (32.35%) in Ningxia, 8 species (23.53%) in Gansu, 2 species (5.88%) in Shanxi, 7 species (20.59%) in Neimenggu, 2 species (5.88%) in Tibet, 1 species (2.94%) in Sichuan, Hebei, Shandong, Hubei, Fujian, 3 species (8.82%) in Yunnan, and 2 species (5.88%) in Hainan province. Ecology and biology of common species in Leptoconops were investigated by author from 1986 to 1994. Suggestion of prevention and treatment of Leptoconops was also put forward by the author.

Key words Diptera Ceratopogonidae Leptoconops Holoconops Acanthoconops People's Republic of China.

23-103

NOTES ON THE GENUS MACRONYSSUS KOLENATI, 1858 FROM CHINA, WITH DESCRIPTIONS OF TWO NEW SPECIES (ACARI:MACRONYSSIDAE)
Zhou Houshu, Wang Dunqing¹, Wang Shenrong²
Sanitation and Anti-epidemic Station of Sichuan, Chengdu 610031, China-Fujian Medical College, Fuzhou 350004, China-First Institute of Epidemic Disease Research, Jilin Province, Baicheng 137000, China

This paper notes seventeen species of genus Macronyssus from China, among which Macronyssus emeicasis sp. nov. and M. fujianensis sp. nov. were two new species. The authors revised the generic characters of Macronyssus noted by Radovsky (1967), and erected three species-groups in this genus.

Macronyssus emeicasis sp. nov.

The new species closely resembles M. taiyuannensis Tian et Gu, 1992, but with the following differences: The new species with 15 pairs of dorsal-lateral setae, with 1 spine on the fixed digit of chela, with 7 setae on genital-ventral plate.

Macronyssus fujianensis sp. nov.

The new species is in the ventralis-group, and that can be readily distinguished from the other species of the species group.

Key words Acari Macronyssidae Macronyssus
Ichoronyssus species-group new species

23-102

INTRASPECIFIC VARIATION OF IXODES PERSULCATUS,
MAIN VECTOR OF THE LYME DISEASE AGENTS IN
EURASIA (IXODOIDEA: IXODIDAE)

N.A. Filippova

Zoological Institute of the Russian Academy
of Sciences, St. Petersburg, Russia

The multidimensional scaling method by means of software package SYSTAT has been used for estimation of relationships between eight geographical localities (populations) on the basis of morphometrical data. Eleven corresponding characters of males and females have been studied. The differences between the population are retracted only from absolute sizes of organs, whereas their proportions (i.e. shape) were constant in all geographical localities. The largest sizes are typical of populations from relict Tertiary landscapes of Primorski Territory and Altai with which areas of ecological optimum of Ixodes persulcatus coincide. The smallest sizes are observed in European populations near the north-western boundary of the distribution range of the species as well as in Alpine population of Tien-Shan Mountains, near the upper vertical boundary of the of the distribution range.

RECENT ADVANCES IN FORENSIC ENTOMOLOGY IN
ARGENTINA

A. Oliva

Laboratorio de Entomología Forense, Museo
argentino de Ciencias naturales, Buenos Aires,
Argentina

Arthropod succession in corpses at Buenos Aires (34° 36' S) differs somewhat from that accepted by European authors. Winter does not interrupt insect cycles indoors. Phaenicia sericata and Calliphora vicina are the most usual first wave species; the first is present from Spring to late Autumn. Sarcophagidae are not rare as first wave. Ants quickly attack small carcasses, rarely human corpses. Chrysomya albiceps appears in rural environment where it predominates, but also in urban locations. Both this species and C. megacephala have been found from the seventh day onward, and appear to prey on other species. Ophyra sp. appeared on exhumed corpses after four months; indoors after six months; also on exposed corpses. Adults appear to be active in the warm season. Fannia scalaris was often found with the former species, even in urban environment, although said to be a rural species. The phorid Megaselia scalaris was found indoors. Dermestes ater appears after 1 month, D. maculatus after 80-90 days. Necrobia ruficollis is frequent indoors after 1 month; N. rufipes was found in a single instance. Vespula germanica appeared in Patagonia (c. 39° S). Post-Mortem intervals are often shorter than those given by usual reference texts, and approach those determined by Goff and collaborators for Hawaii¹.

AMBLIOMMA TESTUDINARIUM KOCH (ACARI: IXODIDAE) INFESTATION IN GAYALS (*BOS FRONTALIS*) IN BANGLADESH

M.M.H.Mondal, M.Giasuddin¹ and M.K.Islam
Department of Parasitology, Bangladesh Agricultural University, Mymensingh, Bangladesh-1 Bangladesh Livestock Research Institute, Savar, Dhaka, Bangladesh

Amblyomma testudinarium, the tortoise shaped tick is known to occur in a wide variety of hosts in the woodlands from Ceylon (Sri Lanka) and India to Borneo, Indonesia, Thailand, Vietnam, the Philippines, Taiwan, and southern islands of Japan. Recently, the distribution of this tick species has been reported from the north-eastern and south-eastern hills of Bangladesh. The hosts of adult *A. testudinarium* in these areas included pigs and cattle. This report deals with *A. testudinarium* infestation in gayals (*Bos frontalis*) from the hills of Naikhonchari, Bandarban, Bangladesh. The gayals are usually feral but domestication has been possible.

Tick collections from 15 captive gayals at 15 days interval between July 1994 and June 1995 revealed 282 adult *A. testudinarium*. Of them, 99 were female and 183 male with a ratio of 1:1.9. Maximum number of adult *A. testudinarium* on the host body was observed in the dry months (November to February) and minimum in the wet months (June to October). On an average an engorged *A. testudinarium* female weighed 4.5 gm against that of unengorged female (0.9 gm) from the same host. An adult female *A. testudinarium* sucked about 11 times blood than that of *Boophilus microplus*. *A. testudinarium* affected mostly the hidden parts of the body, specially the udder and/or scrotum, and the escutcheon. Because of long mouth parts this tick often inflicted wounds and invasion of maggots occurred.

MALARIA TRANSMISSION IN BINKO A SOUTH SUDAN SAVANNA VILLAGE OF MALI

E.Fondjo¹, A.Touré², A.Dao², D.Sangaré², N.Sogoba², S.F.Traoré², M.Bouaré², M.Diallo², O.Doumbo² and Y.T.Touré².

1. Ministry of Health of the Republic of Cameroon
2. MRTC/DEAP. Ecole Nationale de Médecine et de Pharmacie, Bamako, Mali.

A study on malaria transmission by cross-sectional entomological and parasitological surveys was conducted from June 1994 to January 1995 in the village of Binko located in the South Sudan Savanna area of Mali, 2 km from the irrigated area of the Selingué dam.

The average parasite and gametocyte rates for the children of 2-9 years old were $57.7 \pm 3\%$ and $9 \pm 2\%$ respectively. The parasite rates showed significant seasonal variations ($P < 0.001$), with the minimum of $34 \pm 7\%$ in June and maxima of about $77 \pm 7\%$ in September and January.

An. gambiae s.s. was the main malaria vector found (99.5%, $n=621$). Its mean monthly man biting rate of 101.6 ± 1.2 bites/man/night (b/m/n) showed seasonal variations in relation to rainfall and irrigated rice cultivation pattern. The man biting rate was lower in June (2.38 b/m/n) and higher in August (253 b/m/n). The mean monthly entomological inoculation rate was 69 infective bites/man/month. This rate varied between 5.4 in June and 154 in August. The malaria transmission stability index for the study period was 3.1.

These results categorize Binko as a meso to hyperendemic area with stable malaria.

23-106

THE ROLE OF HOUSEFLIES (*MUSCA DOMESTICA*) IN TRANSMITTING THE MASTITIC AGENT *CORYNEBACTERIUM PSEUDOTUBERCULOSIS* IN DAIRY HERDS IN ISRAEL

Y.Braverman, A.Chizov-Ginzburg, A.Saran, M.Winkler
Kimron Veterinary Institute, Israel

Corynebacterium pseudotuberculosis is a facultative intracellular parasite, characterized by being pyogenic with suppuration and abscess formation in the lymphatic system in many domestic animals. Occasionally abscesses occur in visceral organs and the pathogen may also cause mastitis. Only rare cases of *C. pseudotuberculosis* mastitis in cattle have been recorded, however, our study was conducted in order to assess the role of houseflies in the transmission of *C. pseudotuberculosis* in dairy farms in Israel. The bacterium was isolated in June from 40 wild houseflies collected over a cow lesion and also from 28 laboratory flies fed on infected milk from a mastitic cow. In 10 out of 160 flies dipped entirely into a bacterial broth, the bacterium was recovered from the external body 10 min later. In 10 out of 40 flies fed on contaminated milk the bacterium was recovered from the external body 5 min later. When 110 flies were fed on contaminated sugar cubes, the bacterium was externally recovered from 70 of them 5 min later; from an additional 20 flies it was externally recovered 10 min post feeding. Eighty out of 110 flies excreted bacteria in their saliva from 5 min to 3 h post feeding on contaminated milk. In 40 out of 60 flies bacteria were isolated from their intestine between 1 and 4 h post feeding on contaminated milk. In feces of 30 out of 60 flies bacteria were found between 1 and 4 h post feeding on contaminated milk. In light of these findings and the fact that houseflies have a predilection to feed on milk residues on cow teats, we conclude that this insect plays an important role in the dissemination of *C. pseudotuberculosis* in dairy herds in Israel. In contrast stable flies (*Stomoxys calcitrans*) are not important in the transmission, since following membrane feeding on a mixture of bacterial broth and blood, the bacteria were not recovered after 5, 10, 15 and 30 min and 2 and 24 h post feeding.

23-108

BLOWFLIES (DIPTERA, CALLIPHORIDAE) CAUSED MYIASIS IN THE CENTRAL BLACK SOIL REGION OF RUSSIA

S.P.Gaponov

Voronezh State University, 394000 Voronezh, RF

I investigated cases of myiasis caused by blowflies in 1980-1995. Obligate myiasis caused by *Lucilia bufonivora* Moniez in amphibians (6 cases) and by *Protocalliphora azurea* Fallen (38 cases) as well as *Trypocalliphora braueri* Hendel (33 cases) in some birds. In the Region hosts for *L. bufonivora* were *Rana ridibunda* Pall., *R. esculenta* L., *R. temporaria* L. (fam. Ranidae). 8 species of birds from 5 families (Paridae-2, Muscicapidae-2, Turdidae-2, Sturnidae-1, Hirundinidae-1) are known as hosts for larvae of *P. azurea*. 14 species of birds from 8 families (Paridae-1, Alaudidae-1, Sylviidae-4, Motacillidae-2, Emberizidae-1, Ploceidae-2, Turdidae-2, Sturnidae-1) are hosts for larvae of *T. braueri*. Facultative myiasis caused in mammals (5 species) and man by *C. vicina* R.-D., *Lucilia illustris* Mg., *L. caesar* L., *Phormia regina* Mg. were studied. Hosts for *C. vicina* were *Erinaceus europaeus* L. (2 cases), *Sus scrofa* L. (1), sheeps (5) and man (3). Hosts for *L. illustris* were *Sciurus vulgaris* L. (1), *Sorex araneus* (1), *Alces alces* (1), sheeps (1), man (3). Two cases of myiasis caused in man by *Ph. regina* (1) and *L. caesar* (1) were studied.

23-109

SURVIVAL MODELS FOR *IXODES DAMMINI*E.P. Wileyto¹, S.G. Vail², and G. Smith¹.

1 School of Veterinary Medicine, University of Pennsylvania, New Bolton Center, Kennett Square, Pennsylvania, USA - 2 Department of Biology, William Paterson College, Wayne, NJ, USA

Models of *Borrelia burgdorferi* transmission dynamics must include submodels for survivorship of the *Ixodes* vector. In this paper we summarize the survivorship of *Ixodes dammini* under various combinations of temperature and humidity. We collected replicated cohort survival data for questing larvae, nymphs, and adults. Two kinds of fitting processes were compared: least squares regression and maximum-likelihood for conditional survivorship. Best fits were achieved using a separate model for each combination of temperature and humidity. However, it was possible to fit single models which included temperature and humidity without a serious gain in the sum of squared errors.

23-111

MAGGOT-HEAT VERSUS DAY-HEAT IN ESTIMATING POSTMORTEM INTERVAL

E. P. Catts. Department of Entomology, Washington State University, Pullman, WA USA.

In estimating the postmortem interval (PMI) and the age of maggots and puparia associated with a corpse, the method generally used is the summation of ambient heat units above a lower development threshold for the fly species involved and the comparison of the total units accumulated against known laboratory development rates. However, this method fails to take into account a number of variables that can influence that actual heat experienced by developing maggots.

One such variable, a major one, is the metabolic heat generated by massed maggots. Others include the rate of corpse cooling, solar radiant heat loading of the corpse and substrate and the influence of site topography, air movement, precipitation and overhead cover on microhabitats. Maggot heat dissipated into the corpse bed can influence the rate of development of the subcorpse community. Maggot heat also hinders the arresting of development while the corpse is cooled prior autopsy. However, the summation of heat units appears to work. It is perceived as an accurate, objective and proven method of analysis. The reasons for this will be discussed and areas needing further research identified.

23-110

BIOLOGICAL AND MORPHOLOGICAL ASPECTS OF *LONOMIA OBLIQUA* WALKER, 1855 (LEPIDOPTERA, SATURNIIDAE)L.M.Lorini¹ & E.Corseuil²

1-Instituto de Ciências Exatas e Geociências, Universidade de Passo Fundo, Rio Grande do Sul, Brazil. 2-Instituto de Biociências, Pontifícia Universidade Católica do Rio Grande do Sul, Porto Alegre, Rio Grande do Sul, Brazil.

Of the many Lepidopteran species distributed in south Brazil that may affect human beings with their urticant spines, there is one reported as being responsible for several deaths. These deaths were the result of haemorrhages caused by a toxin released from the caterpillar's spines onto the skin of the victim when touched. In order to determine some of the biological and morphological features of this previously unknown species, laboratory rearing was developed to measure the life span of the eggs, larvae, pupae and adults together with some of their physical features. The mean periods and sizes were as follows. The eggs were laid on the under surface of leaves and were ellipsoid in shape, 2.0 mm long, green in colour becoming darker nearer to hatching which occurred after 17.4 days. The caterpillars were dark brown, with longitudinal brown lines and many spines covering the whole body with colour changing from brown to black. They were gregarious, feeding mainly during the night on leaves of plants like *Platanus acerifolia* and some *Prunus* crop species. The duration of the caterpillar stage ranged from 63 to 76 days. The first larval instar was 5.6 mm long and the last 53.7 mm, and their head capsules were 1.0 mm and 5.0 mm wide respectively. The pupae were dark brown in colour with lengths of 30.2mm in females and 28.7 mm in males, and widths respectively of 10.9mm and 10.1 mm. The duration of the pupal stage ranged from 29 to 141 days. The male adult wings were 60.5 mm in length with yellow as the main colour, adult female wings with 80.2 long and mainly grey. The longevity of males was 5.9 days and females 7.7 days.

23-112

FACTORS AFFECTING THE PROBABILITY OF HOST AND TRAP LOCATION BY TSETSE FLIES (*GLOSSINA* SPP.) ON AN ISLAND IN ZIMBABWE

J.W. Hargrove

ODA/IPMI Tsetse Research Project, Harare, Zimbabwe

Tsetse flies locate their hosts using visual and olfactory cues. Given that both sexes subsist exclusively on vertebrate blood, often in areas with low host density, they must be able to locate their hosts with high efficiency. Measuring this efficiency, and identifying the factors affecting it, is made difficult when the tsetse population density, and changes in it over time, are unknown. An experiment carried out on Antelope Island, Lake Kariba, provides a unique opportunity to produce efficiency estimates. A mark-recapture exercise was carried out over a period of more than four years, and weekly population estimates were obtained for males and females of *Glossina m. morsitans* Westwood and *G. pallidipes* Austen. The flies for marking were captured on ox fly-rounds and this provided an opportunity to estimate their probability of capture on a mobile host. It was found that male *G. m. morsitans* had a higher probability of capture than females of that species, and of both sexes of *G. pallidipes*. There was little difference between the sexes in the probabilities of capture in the latter species. These results can be explained on the basis of the reaction of tsetse to mobile baits in general, and to the presence of men in particular. The probability of capture by traps (either unbaited, or baited with various combinations and doses of acetone and carbon dioxide) showed precisely the opposite pattern; *G. pallidipes* was captured with a higher probability than *G. m. morsitans* and females with a higher probability than males. The effects of climatic variables, season and time of day are investigated.

23-113

CONTRIBUTIONS TO THE KNOWLEDGE OF THE LIFE-HISTORY OF THE *PHARYNGOMYIA PICTA* MEIGEN (DIPTERA, OESTRIDAE), AN ENDOPARASITE OF THE *CERVUS ELAPHUS* LINNAEUS (ARTIODACTYLA, CERVIDAE).

A. Notario, L. Castresana, D. González¹

Departamento de Ingeniería Forestal, E.T.S. de Ingenieros de Montes, Universidad Politécnica de Madrid, Madrid, Spain- ¹ Dirección General de la Conservación de la Naturaleza, Jaén, Spain

Actually, in different zones of Spain, *Pharyngomyia picta* Meigen is relatively abundant and causes sanitary disorders to the *Cervus elaphus* L. populations. For this reason the study of this bot fly can be considered a very important research also under a practical point of view.

Ph. picta lives as endoparasite reaching the larval maturity in the retropharyngeal cavity of the host.

This work tries to give a contribution to the bionomical knowledge of *Ph. picta*, starting from observations achieved in Monte de Lugar Nuevo (Jaén, Spain).

23-115

PICTORIAL KEY TO MAIN SPECIES OF SIPHONAPTERA OF MEDICAL AND VETERINARY IMPORTANCE IN BRAZIL
C.L.Bicho, P.B.Ribeiro¹

Departamento de Zoologia, Universidade Federal do Paraná, Paraná, Brazil - ¹ Departamento de Microbiologia e Parasitologia, Universidade Federal de Pelotas, Rio Grande do Sul, Brazil

With the objective of creating a pictorial key that makes an easy identification of the main species of fleas of medical and veterinary interest, there have been examined, in the course of the year of 1995, specimens of several brazilians institutions.

The species used for the construction of the key were: *Tunga penetrans* (Linnaeus, 1758), *Echidnophaga gallinacea* (Westwood, 1875), *Ctenocephalides felis* (Bouché, 1835), *Ctenocephalides canis* (Curtis, 1826), *Pulex irritans* Linnaeus, 1758, *Xenopsylla cheopis* (Rothschild, 1903), *Xenopsylla brasiliensis* (Baker, 1904), *Leptopsylla segnis* (Schonherr, 1816), *Nosopsyllus fasciatus* (Bosc, 1801) and *Polygenis* spp.

There have been considered, mainly, the following characteristics: eyes, format of the head, occiput seta, genal and pronotal ctenidium, hind coxa, hind tibia, segments thoracic, antesensilial seta and spermatheca.

23-114

ODOUR-GUIDED HOST-FINDING BY HAEMATOPHAGOUS MOSQUITOES: THE EFFECT OF HOST-SPECIFIC ODOURS ON THE BEHAVIOUR OF MALARIA MOSQUITOES (DIPTERA; CULICIDAE).

M.A.H. Braks, W. Takken

Department of Entomology, Wageningen Agricultural University, Wageningen, the Netherlands.

Female mosquitoes require a blood meal for egg production, and a variety of stimuli are involved in the vital process of location of a suitable host animal, including physical, visual and olfactory. The importance of olfactory stimuli has long been recognized, however, apart from carbon dioxide and lactic acid, no specific compounds have been indentified. By means of two-choice bioassay tests the effect of host-specific odours on the behaviour of members of the *Anopheles gambiae* complex, all acting as vectors of malaria in Africa, are studied. The responses of *Anopheles gambiae* s.s, the most antropophilic member of the complex, to (components of) human emanates are presented.

23-116

IMMUNE RESISTANCE TO TICKS
—STUDIES ON RED CELL IMMUNE FUNCTION OF HOST

Liu Zhigang¹, Ye binghui², Xiong Guoqiang¹, Cui Wang Hua¹

Department of Parasitology (Box 104[#]), Jiangxi Medical College, Nanchang 330006, People's Republic of China - ¹ Department of Parasitology, Nanjing Medical University. Nanjing 210029, People's Republic of China - ².

Since the phenomenon of acquired immune resistance to ticks following infestation was reported by Trager in the late 1930's, the host humoral and cellular immune resistance have been studied by many workers (wikel 1982, 1984, 1994, willadsen 1980, Brow, 1988; Opdebeeck 1994). Yet, it isn't clear what the red cell immune function of the host play in immunity to ticks. This article reports that the changes in RBC immune function of rabbits after re-infestation by *Ixodes sinensis* (Infestation group) and immunization using the SGA of *Ixodes sinensis* (immunization group). The RBC immune function includes C₃b receptor rosette rate (C₃bR)(%), immune complex rosette rate (ICR)(%) and phagocytosis of leukocytes promoted by RBC (%).

The result showed that in control group C₃bR was 6.37 ± 2.51(%), ICR was 8.67 ± 4.62(%), and phagocytosis of leukocytes promoted by RBC was 28.04 ± 6.24(%). The RBC immune function in both groups of infestation and immunization increased dramatically; and phagocytosis of their leukocytes promoted by RBC were 41.86 ± 10.29(%) and 54.21 ± 12.37(%) respectively, being significantly higher than that in control group (P < 0.01). ICR decreased and C₃bR increased as compared with those of the control group (P < 0.05). The paper suggested that the RBC immune function of host play an important part in immunity to ticks, besides antibody, complement, hypersensitivity leukocyte etc..

23-117

HISTOCHEMISTRY AND HISTOPATHOLOGY OF TICKS (*IXODES SINENSIS*) AFTER INFESTING IMMUNIZATION RABBITS.

Liu Zhigang¹, Li jin¹, Ye binghui², Xiong Guoqiang¹, Cui Xiaomin¹

Department of Parasitology (Box 104[#]), Jiangxi Medical College, Nanchang 330006, People's Republic of China – 1. Department of Parasitology, Nanjing Medical University. Nanjing 210029, People's Republic of China – 2.

The ticks (*Ixodes sinensis*) fed on immunization rabbits with SGA from the adult female ticks were studied after 1, 2, 3, 5, 8 and 15 days of infestation respectively by using histochemical and histopathological techniques, as well as micrography and imaging analysis.

The histochemical results showed that the reactions of glycogen, protein, nucleic acid (RNA and DNA), AKP, ACP etc. in the immunization group were less than those of the control group ($P < 0.01$). The gray level assessment in tissue imaging showed significant difference between the two groups ($P < 0.05$). The histopathological examination of the *Ixodes sinensis* fed on immunization rabbits showed that the gut was damaged within 8 days. Significant difference was found in gut damages between the two groups. ($P < 0.001$). It is suggested that *Ixodes sinensis* infecting immunization rabbits had significant change on the above histochemical element and histopathological structures, which might be considered as important characteristics in immune to ticks.

23-119

LIFE CYCLE OF *DRYOMYZA FORMOSA* (WIEDEMANN) IN NAGASAKI, WESTERN JAPAN (DIPTERA: DRYOMYZIDAE)

H. Kurahashi and O. Suenaga¹

Department of Medical Entomology, The National Institute of Health. Tokyo, Japan - 1 Reference Center, Institute of Tropical Medicine, Nagasaki University, Nagasaki, Japan

An investigation to know the life history of *Dryomyza formosa* (Wiedemann) was made in Nagasaki, Western Japan from January 1990 to December 1994. A trap baited with horse meat was set at three different altitudes, 5 m, 500 m and 1,000 m, of Mt. Gokahara-dake (alt. 1,058 m). The number of flies captured was counted once a month. Male and female flies appeared in spring (April to May) and autumn (November) at altitude 5 m. The two peaks of fluctuation were also found from April to June and October to November at altitude 500 m. However, no adult was trapped by the lowland traps during summer. One big peak of fluctuation was found in June, and some adult flies were trapped during summer at alt. 1,000 m. Wear of wing suggested the adults trapped at alt. 5 m and 500 m in spring were juvenile and teneral in contrast with old aged ones trapped in autumn. Percent wear of wing increased towards autumn at alt. 1,000 m. Percent females with inseminated spermathecae and % mature ovaries suggested that female flies were not sexually matured before October. Flies collected at alt. 5 m and 500 m in autumn and early winter all were already matured. Immature stages were not found in the trap baited with horse meat, but larvae were reared from human feces at alt. 50 m and 500 m during late autumn. Adults emerged from overwintered pupae on April and May. Juvenile adults emerged in lowland most probably migrate to highlands for overwintering. After aestivation adults matured and migrated to lowlands for laying eggs.

The result of the present field experiment showed that *D. formosa* is an univoltine, short-day insect. Diapausing adult most probably overwinters at the highland more than 1,000 m. After larval growth in late autumn, diapausing pupa overwinters for about 4 months.

23-118

FLIGHT ACTIVITY OF *PHLEBOTOMUS ALEXANDRI* USING A VEHICLE-MOUNTED NET IN THE SULTANATE OF OMAN.

D.M. Roberts

Dept. of Biology, Sultan Qaboos University, Sultanate of Oman.

A vehicle-mounted net was used to collect hourly samples of sandflies on 15 nights during June in northern Oman. *Phlebotomus alexandri* Sinton was the most abundant of the 7 sandfly species collected.

63 % of the *P. alexandri* were female and most were unfed, with only 8 % of the females being blood-fed and 18 % gravid. Of the unfed females, only 9 % were parous.

Activity was almost entirely nocturnal. Apart from the light intensity, a multiple regression showed that the most important factor encouraging flight was low humidity, followed by low wind velocity, and to a small extent, high nighttime temperatures.

During the night, activity was greatest during light intensities < 0.1 lux, although a few males and unfed females were collected up to 1.25 hours after sunrise ($< 50,000$ lux). Both male and female *P. alexandri* showed two peaks of activity during the night, with reduced catches around 01.00h. An exception was the blood fed females, which were largely restricted to the first half of the night (20.00 - 01.00h). Parous females were more abundant during the second half of the night (unlike the nulliparous flies), but the numbers of parous flies collected was too small to be statistically analysed.

23-120

CHARACTERIZATION OF NITRIC OXIDE SYNTHASE EXPRESSION DURING MALARIA PARASITE DEVELOPMENT IN *ANOPHELES STEPHENSI* (LISTON) (DIPTERA: CULICIDAE)

S. Luekhart, R. Rosenberg, R. A. Wirtz

Department of Entomology, Walter Reed Army Institute of Research, Washington, DC USA 20307-5100

In both vertebrate and invertebrate hosts, malaria parasites overcome diverse mechanical and physiological barriers to invasion and multiplication. We know little, however, about interactions between the mosquito and *Plasmodium* and strategies the parasite may use to overcome or evade invertebrate host obstacles.

In vertebrates, nitric oxide synthase (NOS) catalyzes the production of nitric oxide which participates in signal transduction, pathogen destruction, and immune modulation. Using degenerate polymerase chain reaction (PCR) primers to *Drosophila* NOS (DNOS; Regulski and Tully, 1995. Proc. Natl. Acad. Sci. USA 92:9072-9076), we examined NOS expression in *Plasmodium falciparum*-infected *Anopheles stephensi*. High levels of NOS expression were detected at various stages of parasite development.

Sequence analysis of the NOS PCR-amplified from infected mosquitoes indicates a high level of sequence and amino acid homology to DNOS, suggesting that the fragment is derived from the *A. stephensi* genome. Parasite loss during sporogony even in susceptible *Anopheles* implies that inherent refractory mechanisms exist (Rosenberg and Rungsiwongse, 1991. Am. J. Trop. Med. Hyg. 45:574-577). Mosquito anti-*Plasmodium* NO could limit parasite development in a manner similar to vertebrate liver NO (Mellouk et al. 1991. J. Immunol. 146:3971-3976). We are continuing to characterize NOS gene expression in infected mosquitoes and the impact this may have on the success of parasite development.

23-121

USING SATELLITE IMAGERY TO PREDICT THE DISTRIBUTION OF AFRICAN HORSE SICKNESS AND *CULICOIDES* (DIPTERA: CERATOPOGONIDAE) VECTORS IN MOROCCO.

M. Baylis, H. Bouayoune¹, J. Touti², H. El Hasnaoui³

Institute for Animal Health, Ash Road, Pirbright, Surrey GU24 0NF. ¹Laboratoire d'Analyses et de Recherches Vétérinaires de Fes, Morocco; ²d'Agadir, Morocco; ³de Casablanca, Morocco.

Since 1993, 20 sites in Morocco have been monitored for the presence and abundance of *Culicoides imicola* (Diptera, Ceratopogonidae), a biting midge which was the vector of a recent epidemic of African horse sickness (AHS), a highly pathogenic viral disease of equines. The normalised difference vegetation index (NDVI), a remotely-sensed measure of green vegetation biomass, has proven to be a better explainer of the distribution of *C. imicola* than any of several ground-measures of climate, including air and soil temperature, humidity, saturation deficit and windspeed. Using discriminant analysis, the mean annual minimum NDVI (NDVI_{min}) from 1980-1991 correctly predicted the approximate abundance of *C. imicola* at 15 of the 20 sites in Morocco. Furthermore, the Moroccan relationship between NDVI_{min} and abundance successfully predicted the distribution of the vector in Spain. In general, NDVI_{min} is significantly correlated with rainfall and soil moisture and the relationship with the distribution of *C. imicola* may operate via the frequency of breeding sites (wet soil) of the insect. In Larache province of Morocco NDVI_{min} also appears to describe the distribution of AHS outbreaks during the epidemic.

23-123

EFFECTS OF *SIMULIUM DAMNOSUM* S. L. HAEMOLYMPH ON THE SURVIVAL OF *ONCHOCERCA VOLVULUS* THIRD STAGE LARVAE *IN VITRO* AND COMPARISON TO THE POSSIBLE SITUATION *IN VIVO*.

D.V. Barrault, S.L. Kläger, H.E. Hagen, I. Wright, P. Enyong*, P.J. Ham.

Department of biological sciences, Keele University, Staffs, UK.

* Medical Research Station, Kumba, Cameroon.

Motility assays *in vitro* using immune *Simulium damnosum* s.l. haemolymph (infected with: *Escherichia coli* D.31, *Onchocerca ochengi* microfilariae or Lipopolysaccharide) demonstrated that it was more efficient at killing third stage *Onchocerca volvulus* larvae, than control and SHAM (medium injected) haemolymph. The same effect was observed when the haemolymph was boiled, suggesting that heat stable molecules are implicated in the killing mechanism. When the parasites were exposed to haemolymph *in vivo*, by intrathoracic injection, the situation observed was quite different, killing times were far shorter, implying that *in vivo* many other active components were present. Despite this, using transmission electron microscopy, very little ultra structural damage was observed in the parasite. The possible immune mechanisms used by *S. damnosum* s.l. against *O. volvulus* will be discussed.

23-122

THE EFFECT OF RODENT AND HUMAN MALARIA PARASITES UPON THE BLOOD-FEEDING AND REPRODUCTION OF ANOPHELINE MOSQUITOES

H. Hurd, J. C. Hogg, S. L. Carwardine, P. Taylor, N. Jehan
Centre for applied Entomology and Parasitology, Dept. of Biological Sciences, Keele University, Keele, Staffordshire, ST5 5BG,

The blood-meal size taken by anopheline mosquitoes of the same wing length and age has been determined by haemoglobinometry and by measurement of haematin excretion. *Anopheles stephensi*, feeding upon mice infected with *Plasmodium yoelii nigeriensis* take significantly larger blood meals when infected when the infective, gametocyte stage of the blood meal is present. Despite this increase in blood meal size, mosquitoes that become infected with malaria oocysts exhibit a 21-28% reduction in the number of eggs produced during the subsequent gonotrophic cycle. This fecundity reduction occurs at both high and low intensities of infection (<75 oocysts per midgut: 4.4 oocysts per midgut). Examination of the primary ovarian follicles at various intervals post-infected blood meal revealed that infection does not affect the initial development but that a significant number of follicles began to resorb after 24h. Vitellogenin uptake, monitored by grouping according to Christophers' stages is significantly retarded in the remaining follicles. These results are being confirmed using an ELISA.

Field studies conducted in Muheza, NE Tanzania, have demonstrated that human malaria parasites also significantly reduce the egg production of *Anopheles gambiae* s.l. This pathology may therefore have implications for our current understanding of vector population biology and disease transmission.

23-124

MORPHOLOGICAL, ETHOLOGICAL AND BIOCHEMICAL CHARACTERISTICS OF LARVAE OF *CEPHENEMYIA AURIBARBIS* (MEIGEN) AND *PHARYNGOMYIA PICTA* (MEIGEN)

P. Ferrazzi, L. Rossi¹, S. Demichelis, A. Manino

DI.VA.P.R.A. - Entomologia e Zoologia applicate all'Ambiente "Carlo Vidano", Università di Torino, Grugliasco, Italy - ¹ Dipartimento di Produzioni animali, Epidemiologia ed Ecologia, Università di Torino, Torino, Italy

Cephenemyia auribarbis (Meigen) and *Pharyngomyia picta* (Meigen) (Diptera Oestridae) are two important parasites of the respiratory tracts of the red deer (*Cervus elaphus* L.). Larval identification is usually made by examining external features pertaining to first or third instar larvae.

Morphological examination of second instar larvae showed discriminant characters. In particular the distance between the bases of the fleshy cones of the pseudocephalon is reduced in *C. auribarbis* and wide in *P. picta*; spines are present on the anterior part of the seventh abdominal segment in the former species and lack on the middle dorsal surface of it in the latter.

Moreover, a remarkable difference in the ethology of the first instar larvae was observed: *P. picta* larvae reach the trachea and the larger bronchi and then migrate into the nasal cavities little before the first molt, while *C. auribarbis* larvae always remain in the nasal cavities.

Also the electrophoretic analysis of the tetrazolium oxidase or superoxide dismutase (TO or SOD) enzyme system proved to be a reliable tool for the identification of the two species at the larval stage.

23-125

THE USE OF IMAGE ANALYSIS SYSTEMS IN SIMULIID TAXONOMY

C.A. Lowry, A.J. Shelley, S. Luz and M. Maia-Herzog¹

Medical and Veterinary Division, Department of Entomology, The Natural History Museum, London, U.K. - 1 Departamento de Entomologia, Instituto Oswaldo Cruz, Rio de Janeiro, Brazil Recent work on Neotropical Simuliid vectors of human onchocerciasis, has shown that behavioural and vectorial differences can be attributed to the existence of sympatric populations of closely related species or of species complexes defined by cytological and molecular methods. A search for fine morphological characters for rapid field identification of members of species groups and complexes involves the need for simultaneous comparisons.

The "Synoptics" system of automated imaging of both morphological and chromosomal preparations allows a composite computer image to be constructed from various focal plains of specimens viewed through a microscope. This has surmounted previous problems of microphotographic reproductions that have precluded the full definition of morphological features in a single photograph because of depth of field problems.

This technique has been effectively used in differentiating *Simulium oyapockense* Floch & Abonnenc from *S. roraimense* Nunes de Mello, both vectors of onchocerciasis in the Brazilian Amazon, and from the morphologically similar non vector *S. minusculum* Lutz.

23-127

THE EXPRESSION OF PARASITE ANTIGENS IN THE SALIVARY GLANDS OF THE MOSQUITO, *Aedes aegypti*: A MODEL SYSTEM TO EXAMINE THE POSSIBILITY OF USING HAEMATOPHAGOUS INSECTS TO DELIVER VACCINE ANTIGENSS.L. Stowell, M.A. Hughes, R.E. Sinden¹, J.M. Crampton

Liverpool School of Tropical Medicine, Pembroke Place, Liverpool, L3 5QA, UK - 1 Department of Biology, Imperial College of Science, Technology and Medicine, London SW7 2BB, UK.

A model system has been chosen to explore the concept of vaccine delivery by haematophagous insects. The vaccine:insect combination selected to model and assess this novel possibility is:

- the transmission blocking antigen, Pbs21 which is expressed on the surface of the rodent malaria parasite *Plasmodium berghei* during zygote and ookinete stages of development and
- the mosquito *Aedes aegypti*.

The eventual aim is to produce a transgenic mosquito capable of expressing significant quantities of the Pbs21 antigen in its salivary gland such that a small amount of the antigen protein is delivered to the host, in the saliva, when the female mosquito takes a blood meal. To do this, the cloned gene coding for the Pbs21 antigen, under the control of a salivary gland specific promoter, will eventually be introduced into the mosquito genome using transgenic means.

Recombinant Pbs21 produced by *Spodoptera frugiperda* cells using a baculovirus expression system is highly immunogenic and has previously been shown to induce transmission-blocking activity in mice. Our initial studies have focused on expressing the gene coding for Pbs21 in cultured mosquito cells and salivary glands *in vitro*. The gene transfected into *Ae. aegypti* cultured cells is expressed and the recombinant Pbs21 protein is detectable immunologically. When the Pbs21 gene construct is transfected into cultured *Ae. aegypti* salivary glands, transcripts of the gene are detectable by *in situ* hybridisation, and Pbs21 antigen is also produced. Future studies will determine whether the Pbs21 antigen produced in *Ae. aegypti* salivary glands can induce transmission-blocking activity when introduced into mice.

SPATIAL AND TEMPORAL ANALYSIS OF MALARIA TRANSMISSION PATTERNS USING A GEOGRAPHIC INFORMATION SYSTEM

W.A. Hawley, A.W. Hightower¹, M. Ombok², R. Odhiambo², R. Otieno²

Kenya Medical Research Institute, Nairobi, Kenya and Division of Parasitic Diseases, Centers for Disease Control and Prevention, Atlanta, GA, USA - 1 Division of Parasitic Diseases, Centers for Disease Control and Prevention, Atlanta, GA, USA - 2 Vector Biology Control and Research Centre, Kenya Medical Research Institute, Kisumu, Kenya

Field studies were conducted in 15 villages bordering Lake Victoria in western Kenya, an area of intense malaria transmission. *Anopheles gambiae* complex and *An. funestus* Giles mosquitoes were sampled from over 800 households weekly over a two year period using a simple mosquito trap. Samples of *An. gambiae* complex specimens were identified to species as *An. gambiae* Giles or *An. arabiensis* Patton using PCR. Infection rates with *Plasmodium falciparum* were determined using ELISA for a sample of each of the three malaria vectors.

The Global Positioning System (GPS) was used to map all houses from which adult mosquitoes were sampled, rivers, the lake shore, possible larval habitats, swampy areas, and other physical features. Measurements of latitude and longitude were accurate to within 2 meters; altitude measurements were less accurate. GPS coordinates for each physical feature were entered into the ATLAS-GIS Geographic Information System software package. Analysis of abundance and entomologic inoculation rate for each of the three species in relation to distance from physical features at different seasons showed marked small-scale variability.

23-128

HOST-FINDING OF THE BLOODSUCKING BUG *Triatoma infestans* (HEMIPTERA: REDUVIIDAE), A VECTOR OF CHAGAS' DISEASE: AN OLFACTOMETER STUDY.

A.M. Rose, J. Boeckh

Institut für Zoologie, Universität Regensburg, Regensburg, Germany

The reactions of groups of 50 individuals of second instar *Triatoma infestans* (KLUG) to different sensory stimuli were examined using a T-shaped olfactometer. The air-speed in the olfactometer was approximately 2 m/s. The insects' behavior was measured as: (a) the percentage of insects entering the olfactometer during the course of a 30 minute experiment ('active insects'), and (b) the percentage of these active insects that entered the leg of the olfactometer where a stimulus was presented ('attracted insects'). Without a stimulus, circa 30% of the bugs were activated, and in each leg about 50% of these active insects were found. Laboratory mice or a human hand in the olfactometer activated more than 80% of the insects, and more than 95% of these were attracted.

Other stimulus sources were mostly taken from potential hosts of *Triatoma infestans*. Most effective was a combination of a previously worn cotton sock and CO₂ (concentration in the olfactometer between 0.05% and 0.1%). This combination activated more than 70% of the insects. Ca. 90% of these were attracted. A worn sock alone activated almost 60% of the bugs, and ca. 90% of them were attracted as well. These values were also obtained using a cotton cloth impregnated with the ethanol extract of a worn sock. Less effective were, among others, between 0.05% and 0.1% CO₂ alone (less than 60% activated / ca. 65% of these attracted), a mouse-nest (ca. 45% / ca. 90%), a skin extract obtained from M. GEIER (University of Regensburg) that is highly effective in the mosquito *Aedes aegypti* (ca. 35% / ca. 75%), and dried human saliva (ca. 35% / ca. 60%). Not effective was, among others, dried human urine. None of these stimuli was found to be as effective as a natural host.

A cotton cloth impregnated with 2 gr. of lactic acid alone did not seem to have any effect on the bugs' behavior. A combination with CO₂ (between 0.05% and 0.1%) activated as many insects as CO₂ alone. However, it was impossible to observe a significant attraction towards these combined stimuli. This was the only instance when an activation without attraction was observed.

23-129

THE ROLE OF CARBON DIOXIDE IN HOST FINDING BEHAVIOUR OF THE YELLOW FEVER MOSQUITO *Aedes Aegypti* (DIPTERA: CULICIDAE): A WIND TUNNEL STUDY

B. M. Steib, J. Boeckh

Institut für Zoologie, Universität Regensburg, Germany

The effect of carbon dioxide stimuli on the behavioural response of female *Aedes aegypti* (L.) was tested in a Y-shaped wind tunnel as described by GEIER (PhD thesis, Regensburg 1995). CO₂ was presented alone in different concentrations, either continuously or pulsed, and in combination with lactic acid and 1-octen-3-ol.

Carbon dioxide of 8 different concentrations (0.001 - 6 vol-% above ambient air and 100 %) was added to a test air stream. Mosquitoes started to respond to carbon dioxide within the range of 0.01 to 0.2 vol-%. Carbon dioxide elicited significant activation (mosquitoes having left the starting cage) as well as attraction (mosquitoes in the test cage). More than 0.2 % carbon dioxide in the test air stream did not increase the number of responding mosquitoes. At the saturation level an average of more than 60 % of the test animals flew upwind and about 40 % arrived in the test cage. No response differences were observed when the CO₂ stimulus was presented either continuously or in intermittent pulses (pulse durations 13 - 0.13 s). CO₂ acts as a synergist for lactic acid (SMITH et al. (1970) *Ann. entomol. Soc. Am.* 63: 760-770), but when the background CO₂ concentration was reduced, lactic acid turned out to be attractive even in the absence of carbon dioxide. No synergism of CO₂ could be found with octenol, which was neither attractive singly nor did it increase the effect of carbon dioxide.

These results support the assumption that CO₂ alone can act as an activator and attractance. In the Y-shaped olfactometer it is not required to pulse the CO₂ stimulus in order to enhance the response. In contrast to previous studies (ACREE et al. (1968) *Science* 161: 1346-1347) it could be demonstrated that inspite its synergistic impact, carbon dioxide was not essential for the attractive effect of lactic acid.

Y-shaped wind tunnel

NOTES ON THE INCIDENCE OF THE *LUCILIA* GENUS (DIPTERA: CALLIPHORIDAE) IN UMBRIA, CENTRAL ITALY. A CASE OF MYIASIS BY *LUCILIA AMPULLACEA* (VILLEN 1922) IN *TESTUDO GRAECA*.

M. Principato, A. Cioffi

Istituto di Parassitologia, Facoltà di Medicina Veterinaria, Perugia, Italy

During the period 1990-1995, we carried out some surveys on the incidence of the *Lucilia* genus in Umbria, enabling us to identify the main species present in our region: *L. sericata* (45%), *L. Richardsi* (22%), *L. illustris* (16%), *L. caesar* (9%) and *L. ampullacea* (2%), (other species 6%). These insects can cause facultative myiasis, generally following an altered physiological state of the host animal, for instance in case of diarrhea, nasal or vaginal leakage and above all of traumas. In the last few years in Umbria, various and recurrent cases of myiasis were recorded by us: dermal myiasis in sheep by *L. sericata*; dermal myiasis in dogs by *L. illustris* and *L. sericata*; aural myiasis in a rabbit by *L. caesar*; rectal myiasis in a cat by *L. sericata*.

A particularly interesting myiasis by *L. ampullacea*, a quite rare species in Umbria, was observed in a terrestrial turtle (*Testudo graeca*), which had been bitten by a dog in the month of August. *L. ampullacea* had effected three cycles of ovoposition in the animal's healthy skin plicae, under its shell and on its limbs, near the traumatic wound. A total number of 480 larvae at the first, second and third instar was counted. The larval development from the first to the third instar was obtained in laboratory at 29°C and 80 RH in just 3 days. Our successful therapy required the removal of all larvae from the lesion, which was kept open and was inspected for three days. As far as we know, that is the first case of myiasis by *L. ampullacea* recorded in Italy.

23-130

ISOLATION OF PATHOGENIC BACTERIA FROM *ALPHITOBIVS DIAPERINUS* (PANZER) (COLEOPTERA: TENEBRIONIDAE), A PEST OF POULTRY HOUSES.

M. Principato, V. Cuteri¹

Istituto di Parassitologia, Facoltà di Medicina Veterinaria, Perugia, Italy

¹ Istituto di Malattie Infettive, Facoltà di Medicina Veterinaria, Perugia, Italy.

Alphitobius diaperinus is a darkling beetle, recently recorded by us in Italy for the damages caused by its larvae to poultry house insulation. Moreover, the larvae can harbour various pathogens of poultry and since they are found in a very great number in litters, that is a serious hygienical problem above all in broiler houses. In order to verify the pathogenic role of these beetles, we have effected four samplings (at about 15 days' intervals) of larvae and adults in an Umbrian broiler house massively infested. The insects were dipped in 1% formaldehyde for 1 minute and were dissected, in sterility conditions, to extract their content. This was cultured in Trypticase Soy Broth (BBL) at 37°C for 12 hours. Afterwards, cultures in Trypticase Soy Agar and Trypticase Soy Agar with addition of sheep defibrinated blood (5%) and Mac Conkey Agar (BBL) were made. The bacteria so developed were identified by biochemical and serological tests. *Enterobacter cloacae* was always isolated from larvae, whereas from adults *Streptococcus dysgalactiae* was isolated twice, *Staphylococcus intermedius* was isolated once and once the sampling turned out to be sterile. *E. cloacae* is a microorganism frequently isolated either from human or avian intestine, but it is not considered to be enteropathogenic. On the contrary, *S. dysgalactiae* and *S. intermedius* can cause pneumonia, conjunctivitis, otitis and urogenital infections to poultry.

23-132

MALLOPHAGA MENOPONIDAE: NEW PARATENIC HOSTS OF *SYNGAMUS TRACHEA* (NEMATODA: SYNGAMIDAE) IN *ALECTORIS RUFA*

M. Principato

Istituto di Parassitologia, Facoltà di Medicina Veterinaria, Perugia, Italy

It is known that *Syngamus trachea*, a parasite frequently occurring in the respiratory apparatus of fowls, can have a direct or an indirect life cycle. That is important from an epidemiological point of view because the intermediate host can harbour parasites for long. The usual intermediate hosts of *S. trachea* are earthworms (*Annelida*), which swallow the parasite's larvae by feeding on infected faeces on the ground. We could demonstrate that also biting lice (*Mallophaga*) can be paratenic hosts of *S. trachea*, like earthworms. Our observations started with a case of a red-legged partridge (*Alectoris rufa*) infested by *S. trachea*, also showing a severe infestation by biting lice. At a microscope examination, five of those insects also showed the presence of nematode larvae, presumably *S. trachea*. To reach an exact identification, we carried out an experiment consisting in making a healthy sample of partridge swallow four biting lice containing nematode larvae, still alive. The larval migration of the nematodes could not be observed, for the experiment was effected on just one bird, but two weeks after the laboratory contamination, at least two specimens of *S. trachea* adults were observed in the bird's trachea; after the 22nd day eggs of the nematode were present in the bird's faeces. If we consider that *Mallophaga* are obligatory parasites of fowls and they do not feed on earth contaminated by faeces, as earthworms do, it can be assumed that their infestation can occur when the host's feathers and skin are dirty of faeces containing a high number of *S. trachea* eggs.

23-133

HUMAN SKIN MYIASIS BY *GASTEROPHILUS INTESTINALIS* (DE GEER) (DIPTERA: GASTEROPHILIDAE) IN UMBRIA, CENTRAL ITALYM. Principato, J. Azzopardi, V. Cuteri¹

Istituto di Parassitologia, Facoltà di Medicina Veterinaria, Perugia, Italy

¹ Istituto di Malattie Infettive, Facoltà di Medicina Veterinaria, Perugia, Italy.

The oral and gastric myiasis in horses by *Gasterophilus intestinalis* is, in Umbria, the most frequent parasitosis of those caused by the other four *Gasterophilus* species we have recorded in this region. The infestation occurs in the 96% of half-free-ranging horses, with a parasitic charging potential that, already in February, reaches N.450 larvae in the host's stomach. Reported herein for the first time in Umbria are three cases of human skin myiasis caused by *G. intestinalis* first instar larvae, recorded in 1994 and in 1995, from the end of October to mid-November, in people who had ridden horses still infested by *Gasterophilus* eggs. The initial stage of the parasitosis was characterized by the formation of a very itching tiny blister leading to scratching. Then a well visible small channel formed, followed by painful swelling and a suppurative process by *Streptococcus pyogenes*. The result was an open lesion, out of which blood serum and pus leaked. The most affected areas (with 7/10 larval attacks) were the thighs, the calves and the pelvis. Lesions on the arms were rare. The recovery was obtained after squeezing lesions up to the complete removal of parasites (dead) and after giving Tetracycline. We think that, from an epidemiological point of view, the period October/November is a particularly dangerous moment, since those *Gasterophilus* larvae that could not reach the host are led to do an extreme attempt of adapting themselves by penetrating any host within their range.

23-135

NEW ECOLOGICAL FEATURES OF *Aedes aegypti* (L.) (DIPTERA: CULICIDAE) AND THEIR CONSEQUENCES ON DENGUE TRANSMISSION CYCLESF. Fouque, J. M. Reynes, R. Carinci, P. Gaborit, E. Telliam¹ and J. Fargette¹Laboratoire d'Entomologie médicale, Institut Pasteur de Guyane, Cayenne, French Guiana - ¹ Laboratoire de Virologie, Institut Pasteur de Guyane, Cayenne, French Guiana

The mosquito *Aedes aegypti* is the only vector of dengue in French Guiana where this disease is endemic since many years. The ecological preferences of *Ae. aegypti* were supposed to be well known, and out of Africa this species was generally recognized as urban, almost exclusively anthropophilic and as a good vector but not a reservoir for dengue viruses.

However, during a two-years survey of the dengue situation through entomological data in French Guiana, *Ae. aegypti* was found not only into urban environment, but also into rural and wild environment, even breeding into the rain forest. The anthropophilic rates were found to be less than 0.5, implying that *Ae. aegypti* commonly feed on non-human hosts. Furthermore, a vertical transmission rate of dengue viruses of 1 infected mosquito per about 2000 tested mosquitoes was found, suggesting that *Ae. aegypti* can also behave as a reservoir for dengue. These findings arise the question of the existence of a selvatic cycle of dengue into the rain forest of French Guiana. Though, a selvatic cycle of dengue in America has not been demonstrated, the ecology of *Ae. aegypti* is not a limiting factor.

FORENSIC ENTOMOLOGY IN SWITZERLAND.

C. WYSS⁽¹⁾, D. CHERIX⁽²⁾, J. FAUCHERRE⁽²⁾, A. FREITAG⁽²⁾⁽¹⁾ Criminal Police, Lausanne, Switzerland⁽²⁾ Museum of Zoology, Lausanne, Switzerland

Forensic entomology was initiated in the Canton de Vaud (Switzerland) in 1993. Since that time, 31 cases have been analysed. About 15 species of flies (Diptera), mainly belonging to the genera *Calliphora*, *Lucilia*, *Sarcophaga*, *Fannia*, *Piophilina*, *Megaselia* and *Hydrotaea* were collected. Different samples of these species were reared in order to determine the postmortem interval (PMI). Using data from the literature as well as laboratory data, PMI was successfully determined in most cases. The discovery of *Chrysomya albiceps* (Wiedemann) (Calliphoridae) was rather surprising. Moreover, *Syrphid pipiens* (L.) (Syrphidae) found on carrion in two cases, has not been considered until now as a forensic species. Detailed analysis of two cases will be presented and discussed.

23-136

A GENETIC ANALYSIS OF THE MELANOTIC ENCAPSULATION PHENOTYPE OF A *PLASMODIUM*-REFRACTORY STRAIN OF *ANOPHELES GAMBIAE*

M. J. Gorman and S. M. Paskewitz

Department of Entomology, University of Wisconsin, Madison, Wisconsin, U.S.A.

A genetically selected *Plasmodium*-refractory strain of *Anopheles gambiae* melanotically encapsulates many species of *Plasmodium*. Genetic studies of this refractory strain and a selected susceptible strain have shown that the refractory phenotype is controlled by a limited number of genes. A model system that uses CM-Sephadex beads instead of the malaria parasite has the potential to simplify studies of the genetic mechanism of this immune response. We have recently shown that the bead melanization phenotype has a similar pattern of inheritance to the *P. cynomolgi* B encapsulation phenotype, and, in collaboration with A. Cornel and F. Collins (CDC, Atlanta, GA), that these two encapsulation phenotypes have a common genetic mechanism. Genetic mapping experiments suggest that a major gene involved in the melanization response is located on the right arm of the second chromosome. Results of genetic mapping using RFLP and microsatellite markers from 2R will be reported. In addition, results of an analysis of encapsulation responses to beads with various characteristics will be discussed in regard to possible molecular mechanisms of the encapsulation phenotype.

23-137

ODOUR-GUIDED HOST FINDING BY HAEMATOPHAGOUS MOSQUITOES: OLFACTORY BASIS OF ANTHROPOPHILIC AND ZOOPHILIC BEHAVIOUR.

L.V.F. Van den Broek, C.J. Den Otter.

Sensory Physiology Group, Department of Animal Physiology, University of Groningen, The Netherlands.

Sibling species of the *Anopheles gambiae* complex show different host preferences. *An. gambiae* s.s., the main vector of malaria in Africa, is the anthropophilic member of the complex, *An. arabiensis* is opportunistic, biting both man and cattle, while *An. quadrimaculatus* is reported as zoophilic. Host-seeking is primarily mediated by olfaction. The present study aims at determining whether or not the host choices of these species are reflected in sensitivity and specificity of peripheral odour receptors.

In *An. gambiae* and *An. arabiensis* single cell electrophysiological recordings were made from antennal olfactory neurons on application of some odour substances known as host attractants. Spike recording sites were at the bases of sensilla trichodea. In *An. gambiae* and *An. arabiensis* the following compounds were tested: 1-octen-3-ol, butanone and 3-methylphenol (cattle odours) and the fatty acids C2, C3, C4, C5, iso-C4, iso-C5, laetic acid and a mixture of long-chain acids C6 - C12 (found in human sweat) and CO₂.

The two species gave similar results. No responses to long-chain fatty acids and CO₂ were found. On stimulation with the other substances, mainly excitatory responses were recorded, both short- and long-lasting, but also inhibition or excitation followed by inhibition were found. Some neurons only responded to short-chain fatty acids, in particular to C3 - C5, and not to the other compounds tested. Other cells reacted to both types of compounds. Results will be discussed in more detail at the poster.

23-139

FORENSIC ENTOMOLOGY IN SOUTHERN ITALY: THREE CASE STUDIES.

F. Introna jr., C.P. Campobasso, A. Di Fazio.

Institute of Forensic Medicine - University of Bari - ITALY.

Three case of forensic interest regarding the estimation of Postmortem Interval by entomological data are presented. The Three cases concerning criminal investigations were performed in Southern Italy by the Entomological Lab of the Institute of Forensic Medicine at the University of Bari. For each case the Authors present a description of the remains as observed at the crime scene and a detailed description of the arthropods collected from the remains. The PMI estimation was considered primarily from the stage of decomposition of the body and then from the interpretation of arthropod succession patterns. For each case the collection of insects was performed at the discovery site and during autopsy procedures. In the first case a PMI of 5 to 8 days was established based on the presence of adult specimens of *Histeridae*, *Sarcophagidae* and mature larvae of *Crysomya Rufifacies* (3rd instar). In the second case on the remains of a corpse partially burnt larvae in different developmental stages of *Sarcophaga Haemorrhoidalis* and *Phormia Terranova* were observed; a PMI of 3 to 4 days was then estimated on entomological data. In the third case a PMI of 24 to 36 hours was defined by the evidence of a *Calliphora Vicina* II instar on the body. Details on the laboratory techniques used for each case are reported. In all cases forensic significant conclusions on PMI were obtained by entomological evidence.

23-138

URATE IN THE BLOOD-SUCKING BUG, *RHODNIUS PROLIXUS*: ANTIOXIDANT ROLE IN THE HEMOLYMPH AND REGULATION OF SYNTHESIS IN THE FAT BODY

A.V.G. Souza¹, M. Demasi², E.J.H. Bechara², J.H. Petretsky³, M.A.C. Silva-Neto¹ and P.L. Oliveira¹

(1) Departamento de Bioquímica Médica, ICB, CCS, Universidade Federal do Rio de Janeiro, Rio de Janeiro, RJ, Brasil. (2) Departamento de Bioquímica, Instituto de Química, Universidade de São Paulo, São Paulo, SP, Brasil. (3) Escola Técnica Federal de Química - RJ, Rio de Janeiro, RJ, Brasil.

Heme is a powerful catalyst of the formation of reactive oxygen species. We have recently proposed that blood-sucking insects suffer an intense oxidative insult as consequence of the hydrolysis of large amounts of hemoglobin after a blood meal (Oliveira et al., J. Biol. Chem. **270**, 10893, 1995). Here we show that very high concentrations of urate (2-5 mM) are found in the hemolymph of the blood-sucking bug, *Rhodnius prolixus*. TRAP assay experiments were used to demonstrate that urate is in fact the main free radical scavenger found in hemolymph of this insect. Oxidative insults such exposure to high O₂ atmosphere or hemin injection into the hemocoel resulted in increased urate levels in the hemolymph. These elevated concentrations are due to up-regulated urate synthesis in the fat body, as its secretion is completely abolished by allopurinol. The hemin-induced stimulation of urate synthesis pathway is mediated by the concerted action of protein kinases A and C. Specific inhibition of protein kinase A potentiates the increase of urate synthesis observed following exposure of the fat body to hemin. On the other hand, inhibitors of protein kinase C prevented the hemin-evoked urate release. Taken together, our data suggest that urate is a major antioxidant protection after a blood-meal in this insect.

Supported by CNPq, Finep, FAPERJ and PADCT.

23-140

MORPHOMETRIC STUDIES ON *CULEX PIPIENS* ITALIAN POPULATIONS (DIPTERA, CULICIDAE)

G. Sabatinelli¹ and V. Petrarca²

¹ Istituto Superiore di Sanità, Laboratory of Parasitology, Rome

² University of Rome "La Sapienza", Institute of Parasitology

Culex pipiens Linnaeus is the most important mosquito of medical importance in Italy. This species is an important nuisance factor, a vector of dog filariasis and a potential vector of arboviruses. Two biological forms are present in Italy; one is anthropophilic, autogenous and stenogamous, generally breeding in under-ground, polluted waters in urban areas, and the other is ornitophilic, anautogenous and eurygamous, generally breeding in above-ground, unpolluted waters in rural areas. The identification of the two forms is important to plan selective control actions aimed to reduce the use of insecticides. Siphonal index of larvae is one of the most used character to discriminate the two forms.

Since 1980 we studied larval morphology of the Italian populations of the so-called "urban" and "rural" forms of *Cx. pipiens*. We collected about 30 natural populations of *Cx. pipiens* in different parts of Italy. The exuviae of the 4th larval instar were mounted. Lengths (valves not included) and widths (at the base) were measured, and siphonal indices were calculated (length/width). Nearly 4,500 specimens were measured.

The means of the siphonal indices of the natural populations ranged from 3 to 4.43. The populations of the "urban form" have means < 3.5 and "rural" populations > 3.8, in agreement with results from other Mediterranean countries (Roubaux E., 1945. Bull.Soc.Path.exot., 38: 47-60; Callot J., 1947. Ann.Parasitol.Hum.Comp. 22: 380-393; Senevet G. and Andarelli L., 1954. Arch.Inst. Pasteur Algerie, 32: 36-70).

To assess the possible influence of the environmental and sexual factors on the size of siphon and on the siphonal index, we reared larvae (1,392 specimens), from field-collected eggs of the "rural form" in different laboratory conditions: 15 and 30 °C; high and low densities. Results showed that larvae reared at high temperature and in crowded conditions have shorter siphon and a lower siphonal index than larvae reared at low temperature and in low density conditions. Males (275 specimens) and females (330 specimens) did not show differences in the siphonal index in two out of three experiments, as observed in Spanish populations (Eritja R. and Aranda C., 1995. Mosq.Syst., 27: 73-77).

23-141

COMPUTER-BASED IDENTIFICATION OF THE ITALIAN MOSQUITOES (DIPTERA: CULICIDAE)

R. Romi, G. Sabatinelli and G. Pontuale

Istituto Superiore di Sanità, Laboratory of Parasitology, Rome, Italy

To provide the Italian National Public Health Agencies with a practical tool for identification of the 62 species of Italian mosquitoes, we have developed a computer-based expert system. The software was created using the DELTA system and it runs on IBM PC-compatible computers running MS-DOS or MS-Windows.

The electronic key is an interactive program (INTKEY) for identifying a specimen by comparing its attributes with stored description of taxa. However, some species that are morphologically very similar can only be identified up to group level. The user can identify species by checking a maximum of 67 characters for larvae and 75 for adults and identify genera by checking a maximum of 7 characters for eggs and 12 for pupae. Using a microscope, the user enters his observations about the specimens to be identified as prompted by computer menu. Morphological characters are fully illustrated and can be selected by simply clicking with the mouse. Taxa whose descriptions do not match the specimens are eliminated until reaching the identification. INTKEY program can display the characters in order of their effectiveness at the current stage of the identification, but the user can scan character menu and select the most suitable or available character. When an identification is reached, information about distribution, biology and medical importance of the mosquito can be displayed.

The package has been field tested and works accurately. It is very useful to beginners for quick and correct identification and it familiarizes the users with all required morphological characters. It has proven to be an excellent training tool for entomologists and public health workers.

The knowledge base can be expanded and refined and we plan to extend it to include other arthropods of medical importance in Italy.

The INTKEY package (data and program) can be obtained from Istituto Superiore di Sanità, Laboratory of Parasitology, Viale Regina Elena 299, 00161 Rome, Italy, Fax. (+39-6) 44.69.823. Registration of INTKEY is necessary after a trial period.

23-143

MAGGOT THERAPY FOR THE TREATMENT OF A SEVERE SKIN INFECTION IN A PATIENT WITH GANGRENE AND OSTEOMYELITIS

K.Y. Mumcuoglu, M. Lipo, I. Ioffe-Uspensky, J. Miller, R. Galun

Dept. of Parasitology, Hebrew University-Hadassah Medical School, Jerusalem, Israel.

A 75-year-old male patient was suffering from gangrene with osteomyelitis in his right foot. The tissue surrounding the toes and the sole of the foot up to a depth of approximately 2 cm was heavily infected with bacteria such as *Proteus mirabilis*, *Enterococcus spec.*, *Providencia stuartii* and *Staphylococcus spec.* (coagulase positive). Although the patient has been treated with antibiotics, due to the spread of the infection, two options were offered to him: amputation of the foot or maggot therapy. After receiving his consent, larvae of the sheep blowfly *Phaenicia (Lucilia) sericata* were used for the treatment. During a period of seven months and in 48 applications, approximately 6,000 sterile larvae, 24-48-hours-old, were placed on the wound of the patient. The larvae were left for 3-4 days and removed later as 3rd. instar larvae. After 4 months of treatment, the decaying tissue surrounding the toes and on the bottom of the foot detached from the living tissue. In the last 3 months of the treatment the larvae cleaned the remaining infected tissue. As the therapy progressed, new layers of tissue developed over the living tissue and the accompanying strong odor of the decaying tissues and pain from which the patient suffered intensively, decreased significantly. By the end of the therapy, a year after the appearance of the wounds in his foot, the patient was able to walk again. Maggot therapy can be recommended in cases where antibiotics and surgery are ineffective.

23-142

CURRENT STATUS OF THE STUDY OF MYIASIS (not screw-worm) IN THE MEXICAN REPUBLIC.

M.T. Quintero 1, L.M. Rojas 2, M.E. Ramírez 1, O. Pareja 1 C. Garrido 1, J.L. Bernal 1.

1. Departamento de Parasitología, Facultad de Medicina Veterinaria y Zootecnia, Universidad Nacional Autónoma de México. 2. Comisión México Estados Unidos para la prevención de la Fiebre Aftosa y otras enfermedades exóticas. México D.F.

The objective of the present study is to specify which genus and species of flies (not screw-worm) are affecting as myiasis various animals in the Mexican Republic until 1992-1995. The material consisted in larvae of flies sent to The Mexico United States Commission for the prevention of Aphtose fever and other exotic diseases of animals, the larvae were sent in trial flasks with alcohol at 70° for their preservance each sample had a series of data such as origin animal species date on type of wound out which the larvae had been isolated. As for the study and identification of larvae, the method of boiling it in lactophenol as well as dehydrating it in alcohol of different grades was followed so as to accomplish its later mounting between porta and cover objects by employing synthetic resin. The results obtained up to now have been found the following genus and species of flies: *Phormia regina* in animals from the 14 states of the Mexican Republic; *Cochliomyia macellaria* from 10 states; *Phaenicia sericata*, *Phaenicia cuprina* and *Sarcophaga* sp from 9 states; *Dermatobia hominis* from 6 states; *Musca domestica* from 5 states; *Chrysomya rufifacies* from 3 states. The types of wound in which larvae had been found were mainly; another type of wound; dehorning, tailing and castration. It is conclude that in 17 states of the Mexican Republic althrough 1992-1995, 8 species of flies were found affecting mexican animals in the form of myiasis, the most frequent flie being *Phormia regina* in 14 states.

ELECTROANTENNOGRAMS, ACTIVATION AND UPWIND ORIENTATION; THE RESPONSES OF STABLE FLIES (*STOMOXYS CALCITRANS*) TO HOST ODOUR

S. Schofield, and J. Brady

Dept. of Biology, Imperial College, University of London, UK

Electroantennograms (EAGs) were recorded from laboratory-reared male and female *Stomoxys calcitrans* in response to a range of synthetic chemicals known to be electrophysiologically-active for other biting flies. 1-octen-3-ol, acetone and 3-methylphenol, consistently elicited larger electroantennograms than did control treatments; 1-octen-3-ol was the most potent. Factors affecting EAG amplitude included carbon-chain length, functional group, position of functional group, and degree of saturation.

Take-off responses to 1-octen-3-ol, acetone and CO₂ were assessed in a wind tunnel. CO₂ and acetone increased flight activity, with response thresholds between 0.001 and 0.01% for CO₂, and 0.001 and 0.01 µg/l for acetone. At low doses, 1-octen-3-ol did not affect behaviour, but at high doses it was associated with a marked reduction in flight activity.

In-flight responses to CO₂ were assessed by video recording flies as they entered a broad odour plume in crosswind flight. For CO₂, the number of upwind flights increased with CO₂ concentration, with ~80% of flies exiting upwind at 0.1%. Flight velocity decreased with dose, from 180 cm/s in clean air to 135 cm/s at 0.1% CO₂, whereas, over the same concentration range, sinuosity increased from 0.8 %/s to 1.9%/s. Similar trends were apparent for both acetone and 1-octen-3-ol.

23-145

ODOUR-MEDIATED HOST PREFERENCE OF WEST AFRICAN MOSQUITOES (DIPTERA: CULICIDAE): A CHOICE EXPERIMENT BETWEEN HUMAN AND CALF

C. Costantini¹, N.F. Sagnon¹, A. della Torre², J. Brady, G. Gibson, M. Coluzzi²

Department of Biology, Imperial College, University of London, UK; 1 Centre National de Lutte contre le Paludisme, Ouagadougou, Burkina Faso, 2 Istituto di Parassitologia, WHOCC for Malaria Epidemiology, Università 'La Sapienza', Roma, Italy.

Mosquito host preference has traditionally been assessed by determining the blood meal origin of freshly-fed field-collected specimens. The limits of such an approach lie in the difficulty of obtaining an unbiased sample. Moreover, it does not measure the inherent host preference, but rather what is the final, contingent, host selection. A new approach was developed to test for the role of odours in the determination of host preferences, based on a standardised field trial carried out in a village near Ouagadougou, Burkina Faso. Two odour-baited entry-traps (OBETs) were put beside one another in a choice arrangement, and air coming from two tents was drawn into and blown out of the OBETs by fans via air ducts. A man and a calf of similar mass, each concealed in one of the tents, were used as odour baits. The CO₂ concentration gradient between the two traps was taken into account in the experimental protocol. An 'index of anthropophily' was calculated for each species as the weighed mean proportion of mosquitoes caught in the man-baited trap. Species with indices greater than the 0.5 random expectation included *Anopheles gambiae* s.l. (0.96) and *An. pharoensis* (0.68), irrespective of the presence or not of a CO₂ gradient. *Culex antennatus* had an index significantly lower than 0.5 (0.25), while for the *Cx. decens* species group (0.56) the difference was not significant; for the latter the interpretation was complicated by interactions between the CO₂ concentration released and the presence or not of a CO₂ gradient. Species caught in low numbers, but whose trap distribution showed a bias towards the man-baited trap were *An. funestus*, *Mansonia africana*, *Aedes dalzielii* and *Ae. hirsutus*. Conversely, species showing a bias towards the calf-trap were *An. rufipes*, *Cx. duttoni* and *Cx. nebulosus*. *Ma. uniformis* was the only species distributing at random between the two traps. Molecular identification of the *An. gambiae* s.l. samples revealed a marked difference in trap distribution of the two members of the complex present in the study area, *An. gambiae* s.s. and *An. arabiensis*; the latter constituted 92% (*An. gambiae* s.s. 8%) of identified specimens caught in the calf-trap, but only 56% (*An. gambiae* s.s. 44%) of those caught in the man-trap.

IDENTIFICATION OF MALARIA PARASITES IN MOSQUITOES, BY PCR, FROM A STUDY AREA IN GUINEA-BISSAU

A.P. Arez¹, J. Pinto¹, K. Palsson², P. Cravo¹, J. Dinis³, T. Jaenson² & V. do Rosário¹

¹) Centro de Malária e outras Doenças Tropicais/IHMT, Lisboa, Portugal

²) Department of Zoology, Uppsala University, Uppsala, Sweden.

³) Laboratório Nacional de Saúde Pública, Bissau, Guinea-Bissau

Studies were carried out at the end of the rainy season (October-November), in 30 houses of 3 subareas in Antula (254 people). Where presence of mixed infections or presence of gametocytes in some inhabitants of these houses was detected by microscopy of Giemsa stained blood smears, blood fed mosquitoes were collected from within bed nets of the same houses, at early hours in the morning. The objective of the study was to identify malaria parasites in these mosquitoes by nested-PCR.

These mosquitoes were carefully maintained in containers with glucose wet cotton pads for 10-13 days, when dissections took place. Individual midguts were kept in lysis buffer (Tris 40mM pH8.0, EDTA 80mM pH8.0, SDS 2% pH7.2) and proteinase K (50µg/ml) aimed at PCR studies for parasite identification, carried out in the Lisbon laboratory, at a later stage.

Forty-four mosquito's midguts were analysed by nested-PCR and a 39% infection rate was found, including several mixed infections. In every house/room where infected mosquitoes were captured, gametocytes (of the *Plasmodium* species detected in midguts) were observed in blood smears of the inhabitants. A parallel, further identification of malaria parasites by PCR from blood samples from the same residents (n=52), showed a high prevalence of *P. falciparum* single infections (42%), followed by *P. falciparum* + *P. malariae* (12%), *P. falciparum* + *P. ovale* (2%), with one triple infection (2%) alone, 42% being negative.

All the infected mosquitoes were identified by PCR as *Anopheles gambiae* s.s.

Evaluation of the field work, analysis of blood and midgut infection rates per room and house will be presented. The unexpected high rate of mosquito infections will also be discussed.

This work was supported by PRAXIS XXI/2/2.1/SAU/02/94 and by EC/STD3 "Network for field research on Afrotropical malaria vectors". The expert technical assistance of Mr. Marcelino Suna Nabion (CMT, Guinea-Bissau) and Ana Maria Antunes (IHMT, Portugal) is acknowledged. Dr. Georges Snounou (St. Mary's Hospital, UK) and Prof. M. Coluzzi (Univ. La Sapienza, Italy) provided us with oligonucleotide primers for parasite and mosquito identification

PRELIMINARY STUDY OF INFECTION OF GLOSSINA MORSITANS MORSITANS (DIPTERA, GLOSSINIDAE) WITH TRYPANOSOMA BRUCEI BRUCEI GVR 35 (KINETOPLASTIDA, TRYPANOSOMATIDAE) IN MICE CD1.

M.O. Afonso¹, A.P.G. Almeida², J.M. Atouguia³, J. Costa⁴

1-Disciplina de Entomologia Médica (DEM), 2-DEM/Centro de Malária e outras Doenças Tropicais (CMDT), 3-Departamento de Clínica das Doenças Tropicais (DCDT)/CMDT, 4-DCDT.

1,2,3,4- Instituto de Higiene e Medicina Tropical (IHMT), Universidade Nova de Lisboa, Portugal.

The murine model CD1/*Trypanosoma brucei brucei* GVR 35 has been used for the experimental study of trypanosomiasis (Atouguia, et al., 1995, T.R.S.H.T.M. 89: 531-533). Susceptibility of tsetse flies to this model, has not been assessed.

Different groups of *Glossina morsitans morsitans* of both sexes, from a colony kept at the IHMT, were bloodfed on mice previously inoculated with *T. b. brucei* (Atouguia, et al., 1995), at different times between day 4-24 post inoculation (PI). Flies were kept at 26°C, 70% relative humidity, subsequently fed on uninfected mice every 3 days, and dissected from the 15th to the 49th day after the infectious feed (AIF). *Glossina* mortality was high (29%) up to day 15 AIF, remaining low (5-0%) thereafter. Trypanosomes were observed in the midguts from the 15th day, and in the proboscis and salivary glands (SG) from the 22nd day, AIF onwards.

The rate of tsetse infection was 48% (23/48), however, only 12.5% had SG infections and were considered infective. Both rates were similar in male and female flies. All groups of flies feeding on mice from day 4-24 PI became infected and infective. Transmission of trypanosomes to naive mice was observed after day 22 AIF.

Infection of *G.m.m.* with this trypanosome strain, from infected mice and its subsequent transmission is a useful model for the study of trypanosome/vector/vertebrate host interactions.

Acknowledgements: to Prof. A. Grácio for the use of tsetse colony, and technical support of Mrs. Silvia Nunes, Luisa Anselmo and Teresa Casaca.

THE AMINO ACID COMPOSITION OF ANOPHELES STEPHENSI (DIPTERA: CULICIDAE) INFECTED WITH NOSEMA ALGERAE (MICROSPORA: NOSEMATIDAE) COMPARED TO AN IN VITRO SYSTEM

M. Henna, R. Schopf

Institute for Applied Zoology, Ludwig-Maximilians-Universität München, Germany

The amino acid composition of infected and uninfected larvae, pupae and adults of the mosquito *Anopheles stephensi* were analyzed using an amino acid analyzer.

Light microscopical investigation of the development of *Nosema algerae* within the freshly infected first instar larvae up to the adult mosquitoes showed that there were three periods during which the amounts of meronts and sporonts increased and three periods with an increase in the amount of spores.

The appearance of meronts and sporonts of the microsporidia *Nosema algerae* inside the insects coincided mainly with the increase in the concentration of alanine, proline, threonine, histidine and additionally of tyrosine during the development of the sporonts, whereas the amount of alanine and proline decreased during the sporulation of *Nosema algerae*. Tyrosine appeared in the hemolymph of infected *Anopheles stephensi*, this amino acid could not be found in the blood of uninfected insects. The changes in the amino acid composition of infected *Anopheles stephensi* were compared to those in the cell medium RPMI 1640 during the cultivation of infected cells which were derived from *Aedes albopictus*. As a result the in vitro and in vivo systems showed that the amino acid alanine and proline were important for the development of meronts and sporonts of *Nosema algerae*, whereas tyrosine seemed to induce the sporulation of the microsporidia.

23-149

RESERVES AND FLIGHT ENERGY IN FEMALE MOSQUITOES (DIPTERA: CULICIDAE)

I. Knüsel & H. Briegel

Zoologisches Institut der Universität Zürich, Zürich / Switzerland

Three sources of energy are available to female mosquitoes for flight activities: reserves carried over from larval instars, feeding on nectar and plant juices, and blood meals from a vertebrate host. Quantitative analyses have been carried out to compare the nutritional status with the flight performance in *Aedes aegypti*, a vector of yellow fever, and in *Ae. vexans*, a holarctic species. Females were flown to exhaustion on flight mills and analyzed for lipid and glycogen before and after flight respectively. The data were correlated with flight duration and distances that were recorded from the flight mills by computer.

Development of flight performance differed between the two species. In *Ae. aegypti* it reached maximal values within 3 days of eclosion, while in *Ae. vexans* it took 1-2 weeks. These differences are explained in terms of glycogen and lipid reserves of teneral females, high in *Ae. aegypti* and much lower in *Ae. vexans*. This delay in *Ae. vexans* is caused by feeding carbohydrates to increase its lipogenesis and glycogenesis, before extended flight activities are initiated. Carbohydrates are the primary flight substrates in both species, but older females of *Ae. aegypti* divert increasing segments of glucose towards lipogenesis instead of glycogenesis.

Starvation, i.e. access to water only, drastically reduced the flight potential. Furthermore, small-sized females of both species showed equally reduced flight activities because their dietary sucrose was utilized primarily for reserve synthesis.

Ingestion of a blood meal in *Ae. aegypti* suppressed flight activity and flight potential for 1-2 days but later it was resumed, comparable to sugar-fed females.

Supported by the Swiss National Science Foundation.

A POPULATION STUDY OF INDOOR *LUTZOMYIA OVALLESI* AND *LUTZOMYIA GOMEZI* (DIPTERA: PSYCHODIDAE): RELATIVE VECTORIAL IMPORTANCE AND ASSOCIATION WITH INCIDENCE OF CUTANEOUS LEISHMANIASIS IN NORTH-CENTRAL VENEZUELA.M. D. Feliciangeli¹, J. E. Rabinovich²¹ Facultad de Ciencias de la Salud, Universidad de Carabobo, Maracay, Venezuela and Escuela de Malariología, M.S.A.S., Maracay, Venezuela -² Departamento de Investigación, Universidad de Belgrano, Buenos Aires, Argentina.

In the north-central area of Venezuela *Lutzomyia ovallesi* seems to be the main vector of cutaneous leishmaniasis (CL) with *Lu. gomezi* being apparently a subsidiary vector; the former has been found to be dominantly infected with *Leishmania braziliensis* (1.2%) and more rarely with *Le. mexicana* (0.07%) and the latter infected with *Le. braziliensis* (0.47%).

Based on the conversion of 12-hours/night Shannon traps collections to 12-hours/night CDC indoor figures by linear regression, which proved to be statistically significant for both species, the results of the various non-continuous surveys during 4 years were standardized to the average number of indoor female sandflies per house per night.

Crosscorrelation analyses were then applied to female *Lu. ovallesi* and *Lu. gomezi* abundances and monthly precipitation time series. This also proved to be highly statistically significant with a lag of seven month for *Lu. ovallesi* and with a lag of six months for *Lu. gomezi*. An overall dominance of *Lu. ovallesi* over *Lu. gomezi* was observed. Since annual CL information was available for the study period, the rate of new cases per house per year was calculated and a relationship between indoor sandfly abundance and incidence was attempted by linear regression. For *Lu. gomezi* the regression was not significant while the one for *Lu. ovallesi* was highly significant showing a negative intercept. This result implies that, on the average, unless about 800 or more indoor female *Lu. ovallesi* sandflies (estimated with CDC traps) enter each house per year, we should not expect new CL cases at El Ingenio.

This work received a grant from the CEC (Contract T*S3-CT93-0247) and the University of Carabobo (Project FCS-91-044) and was sponsored by PAHO (Caracas, Venezuela),

CATTLE ON GRAIN DIETS IN FEEDLOTS: ITS EFFECT ON THE EXCRETION PROFILE OF IVERMECTIN IN CATTLE FAECES AND ON SURVIVAL AND REPRODUCTION IN THE SCARABAEINE DUNG BEETLE *ONTHOPHAGUS BINODIS* THUNBERG (COLEOPTERA: SCARABAEIDAE)I.R. Dadour, D.F. Cook¹

Zoology Department, University of Western Australia, Western Australia - Entomology Section, Agriculture Western Australia, Western Australia.

Feeding cattle with ivermectin followed by feeding cattle with dietary supplements of grain before market is becoming a more wide spread practice in Australia. Many farmers involved in this practice have noticed a minimal amount of dung beetle activity in the dung produced by cattle in feedlot situations.

When the dung from both grain (feedlot dung) and pasture fed cattle was assessed as a food and reproductive resource for the dung beetle *Onthophagus binodis* Thunberg by bioassay in the laboratory there was a significantly greater number of F1 progeny survive to adulthood from brood masses produced by beetles reared on pasture dung compared with grain dung. The progeny emerging from brood masses produced with pasture dung were significantly larger compared with progeny emerging from brood masses produced with grain dung.

Furthermore, in this study over 5 times higher levels of ivermectin were excreted in the faeces of grain-fed cattle compared with pasture-fed (grazing) cattle. Peak excretion levels of 0.36 mg/kg (grain-fed) and 0.09 mg/kg (pasture-fed) of ivermectin were recorded at 6 and 8 days post-injection (dpi) respectively. The impact of diet on the excretion profile of ivermectin is discussed in the context of studies attempting to demonstrate ecotoxic effects of ivermectin residues in cattle faeces on dung beetles.

INTERSPECIFIC HYBRIDIZATION OF FLEAS AND ITS SYSTEMATIC SIGNIFICANCERui-yu YE, Jin-tong ZHANG¹, Zi-jian ZHANG, Xin YU, Xinru CHEN, Gen-yuan JIN and Zhong-da GONG²

Xinjiang Institute for Endemic Disease Control and Research, Urumqi 830002, CHINA --1. Institute of Microbiology and Epidemiology, AMMS, Beijing 100071, CHINA --2. Institute of Epidemiology of Yunnan Province, Dali 671000, CHINA

A series of interspecific hybridizations including the direct cross, reciprocal cross, the filial inbreedings and the backcross, has been made with *Neopsylla teratoma* Rothschild, 1913 and *Neopsylla sibirica* Ye et Yu, 1993, two morphologically confirmed species, as the parents. A plate-wet filter paper method was employed to get the naked pupae, which made it possible to avert the intraspecific hybridization. The morphology of both the telomere and the bristles on the horizontal arm of st.9 of the male fleas and the bristle order of st.8, were employed as the criteria for the bred progeny.

The crossability and cross-compatibility have been proved between the two species by direct- and reciprocal crosses, and the morphological intermediate types have been observed in the F1 and F2 of direct cross, F1 of reciprocal cross and in the backcross progeny. It means that the reproductive isolation has been broken, implying the parents are two subspecies under the same species with reference to the specific definition.

In view of the fact that the systematics of Siphonaptera (and also other orders of insects) is mostly based on the morphology, it's hard to completely avoid the subjective activities and voluntary treatments, thus the systematic methodology and the criteria of Siphonaptera should be improved with genetic and modern bio-techniques.

23-153

OBSERVATIONS ON BLOOD-FEEDING OF THE GROUND SQUIRREL FLEA *CITELLOPHILUS TESQUORUM SUNGARIS* (JORDAN, 1929) (SIPHONAPTERA: CERATOPHYLLIDAE)

WU Hou-yong, ZHANG Hong-jie, LIU Quan

Department of Vector Biology and Control, Institute of Microbiology and Epidemiology, Beijing, CHINA

Ground squirrel flea *Citellophilus tesquorum sungaris* is the most important vector of plague of the ground squirrel *Citellus dauricus* Pallas in the grassland of the Northern Provinces of China. It displays high host specificity in field. *C. dauricus* is the prime host for *C. t.sungaris*.

Our experiment has demonstrated that this flea not only prefers to ground squirrel but also to Norway rat, guinea pig, clawed jird and human. The higher blood-feeding rates are on these hosts. The average blood-feeding rate on human is 80.03 (70.02-87.24)%. There are different local skin reactions on the experimental voluntary subjects to be bitten by this flea. The reactions may be divided into three types: hyperemic macule, papulation and wheal respectively.

The blood-feeding rate of the new unfed fleas depends upon the days emerged from the pupae. In five days, the blood-feeding rate shows to be increased with the lifetime (days) of fleas. There is a linear relationship between them and the correlation coefficient r is 0.95.

23-155

STUDIES ON THE HOST PREFERENCE OF MOSQUITOES AND IDENTIFICATION OF MOSQUITO BLOOD MEAL BY HEMOGLOBIN CRYSTALLIZATION IN KOREA

C. M. Kim, H. K. Hong

Department of Biology, College of Natural Science
University of Incheon, Incheon 402-749, Korea.

Blood-meal identification of mosquitoes by the hemoglobin crystallization test have been carried out to determine the host preference in Chollanamdo province which is one of the endemic area of Japanese encephalitis and none endemic Kyonggi province in Korea. Standard models of the crystals were primarily established from the blood samples of common vertebrates and domestic animals in the residential areas.

Mosquitoes fed on variety of animals such as cattle, dog, swine, rabbit, rat, chicken and human beings. The results of hemoglobin crystallization tests for the 241 engorged females of *Culex tritaeniorhynchus* collected from Japanese encephalitis endemic area in Chollanamdo province indicated that 116(48.1%) females had fed on cattles, 34(14.1%) on dogs, 21(8.7%) on swines, 15(6.2%) on men and chickens, 13(5.4%) on rats, 2(0.4%) on rabbits and 25(10.4%) on unidentified animals, respectively.

Anopheles sinensis as a vector species of *Plasmodium vivax* malaria in Korea primarily preferred to feed on the cattles(67.8%) and dogs(32.7%) in Kyonggi province and cattles(51.1%), dogs(18.2%) and human(8.9%) in Chollanamdo province, respectively.

Aedes vexans as a vector of *Dirofilaria immitis* preferred to feed on cattles(56%) and dogs(23.9%) than other animals, and *Culex pipiens* showed preference in feeding on cattles and human in both areas.

23-154

HISTOPATHOLOGICAL & FINE STRUCTURAL CHANGES IN MOUSE SKIN AFTER INJECTION OF HONEYBEE AND SPIDER VENOMS

Sang-Hee Shin, Chang-Soo Kang¹, Myung-Jin Moon

Department of Biology, Dankook University, Cheonan 330-714, KOREA - 1 Department of Life Science, Hoseo University, Asan 337-850, KOREA

Histopathological and fine structural changes in the mouse skin after injection of venoms extracted from the honeybee (*Apis mellifera*) and 3 kinds of spiders (a wandering *Pardosa astrigera*, a hibernating *Araneus* species, and orb weaving spider, *Nephila clavata*) were studied with histochemical and electron microscopical techniques respectively.

After injection of the honeybee venom, only a slight edema and contraction of epidermal tissue appeared, and this kinds of pathologic responses diminished one hour after injection, and the wounds were totally healed within 3 days at most cases. By treatment of the spider venoms, not only severe histopathological symptoms such as edema, hyperemia, eruption and necrosis, but numerous fine structural changes were induced concurrently.

It was clear that the mixtures of venom with digestive fluid had more toxic effects than pure venoms extracted from the venom gland alone. So morphological evidences are presented for the role of the digestive fluid creating additional histopathological and fine structural changes.

23-156

SARCOSAPROPHAGOUS INSECTS AS FORENSIC INDICATORS IN SOUTHEASTERN BRAZIL

L.M.L. Carvalho¹, A.X. Linhares¹, F.A.B. Palhares²

1 - Instituto de Biologia, Departamento de Parasitologia, Universidade Estadual de Campinas, Campinas, Brazil 2 - Faculdade de Ciências Médicas, Departamento de Medicina Legal, Universidade Estadual de Campinas, Campinas, Brazil

The study of the arthropod fauna associated to human remains is very important, for it provide usefull information on causes and circumstances of death. However, very little is known about this subject in the Neotropical Region. A study was undertaken in association with the Medicolegal Institute in Campinas city, Southeastern Brazil in order to determine the arthropods found or in human corpses. Six decomposing cadavers found in different sites and circumstances and live and dead adults and immatures of arthropods found in and on the remainings were collected. The live immatures were reared up to adult to make identification easier. Several especimens belonging to the orders Diptera, Coleoptera and Hymenoptera were collected from four corpses. The two remaining cadavers, one recovered from a body of water and the other burried in cement, did not have any arthropod. Through the results, the post mortem intervals were estimated and they were similar to those obtained by other methods.

23-157

URBAN POPULATION OF THE BLOOD-SUCKING MOSQUITOES

Gluschenko N.P.

Institute of Systematics and Ecology of Animals, Siberian Branch of Russian Academy of Sciences, Novosibirsk, Russia

Urban population of blood-sucking mosquitoes consist of species with wide ecological valency and those species, which are adapted to urbanized sites and conducted a transition to synantropical way of life. These species form a main core of urban mosquitoes populations in insect fauna: *Culex p. pipiens* L., *Cx.p. molestus* Forsk., *Anopheles maculipennis* Mg., *An. messeae* Fall., *Aedes flavescens* Mull., *Ae. dorsalis* Mg., *Ae. caspius dorsalis* Mg., *Ae. cantans* Mg., *Ae. vexans* Mg., *Ae. leucomelas* Mg., *Culiseta annulata* Schr., *Mansonia richiardii* Fic.

Mosquitoes *Culex p. pipiens* and *Cx.p. molestus* are absolute dominants in cities and towns of Russia. They follow man in his advance in the new developing territories. Mosquitoes *Cx.p. molestus* have passed completely to endophyllous way of life, adapted to provisional pools in basement cellars of buildings. The species of *Cx. pipiens* became endophyllous, and previously it was typically exophyllous species of low-developed territories. Its' amount has been increasing rapidly in the suburbs of cities and towns. The massive increase of these populations is caused by a human settlements growth and deterioration of sanitary conditions. The anthropophyllous population of mosquitoes are noticed in displaying the following tendencies: activity period of imago and larval populations density increase, acceleration of ontogenesis period, generations' number growth. All the above mentioned features cause the aggravation of epizootological and epidemic situation.

23-159

PHENOLOGY OF ANOPHELES SUBPICIUS GRASSI, AN UNUSUAL VECTOR OF MALARIA IN THE THAR DESERT, INDIA

B.K. Tyagi, R.C. Chaudhary

Desert Medicine Research Centre (I.C.M.R.), Jodhpur, India

Anopheles subpictus Grassi, a major vector of malaria in Indonesia as well as in the Coromandel coastal areas in the south-eastern Indian mainland, is one of the highly prevalent anophelines in India. In the Thar desert, which is currently under the impact of vast physiographic metamorphosis due to extensive canalization, co-exists with other two main malaria vectors, *An. stephensi* Liston and *An. culicifacies* Giles. It occurs only between June and November, and is essentially a monsoon species. It thrives most at an ambient temperature $28 \pm 2^\circ\text{C}$. In typically desert conditions, it breeds prodigiously in open ground ponds, cement tanks, pitchers and the grassy banks of irrigation channels where water gets stagnated. A zoophilic species, it's anthropophilic index is estimated as 13.4. While in the highly irrigated Ganganagar district and parts of Jaisalmer district, its per-man hour relative density is about 20-50 between the period of its occurrence, in the xeric condition of Jodhpur district the relative density is 5-10 PMH only. A nocturnal species, it feeds intensely in two peaks of 8-10 pm and 4-6 am. Three females collected during routine dawn and the all-night man bait collections in some villages at the border of Jaisalmer and Jodhpur districts and under extensive canalized irrigation from the Indira Gandhi Canal, one of the largest canal systems of its kind in a desert ecosystem with over 8000 km network of tributaries and 649 km long canal, are incriminated (0.47%).

EPIDEMIOLOGICAL STUDIES OF MALARIA IN RELATION TO VECTORS IN CALCUTTA

S. Bhattacharya¹, S. K. Saha², K. C. Mukherjee¹

1. Mosquito Research Unit, Dept. of Zoology, Asutosh College, Calcutta, India

2. Directorate of Health Services (Malaria) West Bengal, Calcutta, India

Malaria is endemic in Calcutta. The Anopheline fauna of the Calcutta Municipal Corporation (CMC) area has not been investigated systematically in the recent past under changed urban ecological conditions. In this study we analysed the incidence of malaria cases registered in the Directorate of Health Services (Malaria) West Bengal, Calcutta between 1987 (Total cases 16337) and 1993 (Total cases 18702) in order to find out the transmission pattern of the infections amongst the human populations. Mosquito collections were also made from different places of the CMC area and from different biotopes with a view to know the prevalence of Anopheline fauna. The anopheline fauna is composed of six species of which *Anopheles stephensi*, *An. annularis* and *An. subpictus* are labelled as primary and/or secondary vectors of malaria in India. For the last few decades, the investigators have been referring *An. stephensi* as the only vector of malaria in Calcutta albeit no systematic and indepth study has been done to assess the vectorial potentiality of the other two named anopheline species. Clinical manifestation of the infections were observed in all the years, encompassing all the meteorologically distinguishable three seasons with a pronounced peak in the rainy season (July to October). These observations suggest that there is perennial transmission of the disease and fluctuations in the level of the circulation of the parasites in its maintenance cycle.

LABORATORY BIOLOGY OF FOUR SPECIES OF CARRION BREEDING CALLIPHORIDAE (DIPTERA) IN SOUTHEASTERN BRAZIL

A. M. Souza¹, A. X. Linhares¹.

Department of Parasitology, Campinas State University, Campinas - São Paulo - Brazil - 1.

The decomposition of animal carcasses occurs, in addition to other facts, through the action of necrophagous insects. In Southeastern Brazil four blowfly species *Chrysomya albiceps*, *Ch. megacephala*, *Ch. putoria* and *Cochliomyia macellaria* are considered the most important carrion-breeders. This work determined the growth curves, developmental times for egg, larva and pupa, and fecundity and mortality rates for the species reared at 13, 17, 20, 25, 28, 31 and 35°C. All experiments were done in growth chambers with constant photoperiod and humidity. Larvas were fed artificial insect culture medium and were weighed at 6, 12 or 24 hour intervals, dependig on the age. The results showed that the temperature had significant influence in all aspects studied. The interval between 25°C and 28°C was found to be the most adequate temperature for the development of these species. At 13°C eclosion of the eggs did not occur, and at 35°C the time of development was greatly reduced. However, a high rate of mortality and a low number of eggs per female were observed. These results are important subsidies that can be used in Forensic studies in Brazil.

23-161

USING *Chrysomya albiceps* (DIPTERA: CALLIPHORIDAE) TO ESTIMATE THE TIME OF DEATH IN HUMANS: A STUDY OF FOUR CASES IN SOUTHEASTERN BRAZIL

A. M. Souza¹, A. X. Linhares¹.

Department of Parasitology, Campinas State University, Campinas - São Paulo - Brazil - 1.

The use of carrion-breeding insects in forensic investigations is a common practice in several countries where the basic biology of the necrophagous insect fauna is well-known. In a preliminary study, *Chrysomya albiceps* was the most abundant species visiting and breeding in pig carcasses exposed in the field. This work determines the patterns and times of development for egg, larva and pupa of *C. albiceps* reared at 13, 17, 20, 25, 28, 31 and 35°C. The experiments were done using growth chambers with constant photophase and humidity. The rate of development showed it to be highly dependent on the temperature. At 13°C and 37°C the larval development was not completed. The most adequate temperature range for the complete development of this species was between 25°C and 28°C, with larger numbers of eggs by female. The results were used to estimate the post-mortem interval of four human remains found naturally infested with *C. albiceps* immatures.

23-163

TICKS (ACARI: IXODIDAE) IN MONTENEGRO (YUGOSLAVIA) WITH EMPHASIS ON THE SPECIES *HYALOMMA SAVIGNYI*

M. Milutinović, Z. Mišćević, G. Milosavljević, V. Ivović

Institute for Medical Research, Belgrade Yugoslavia

The faunistic composition, the relative abundance, population dynamics and the sex ratio of four tick species from the *Ixodidae* family, namely: *Ixodes ricinus*, *Rhipicephalus bursa*, *Rhipicephalus sanguineus* and *Hyalomma savignyi*, found in sheep, cattle and dogs are given in the present work.

The species *Hyalomma savignyi* is significant as vector and reservoir of viruses of CCHF and HF with renal syndrom.

23-162

SANDFLIES (DIPTERA, PHLEBOTOMIDAE) OF ENDEMIC FOCUS OF VISCERAL LEISHMANIASIS IN MONTENEGRO YUGOSLAVIA

Z. Mišćević, M. Milutinović, G. Milosavljević, V. Ivović

Institute for Medical Research, Belgrade Yugoslavia

The endemic focus of visceral leishmaniasis in Montenegro is town Bar and surrounding. In this area the most abundance is the species *Phlebotomus neglectus* (major) - vector of kala-azar, followed by *Phlebotomus perfiliewi*, *Phlebotomus papatasi* and *Sergentomyia minuta*. The faunistic composition, the relative abundance, population dynamics, sex ratio and origin of blood meals are given in the present work.

23-164

HETEROCHROMATIN VARIATION IN THE SEX CHROMOSOMES OF SPECIES A OF THE ANOPHELES DIRUS COMPLEX IN VIETNAM.

Lien Giang Ngo¹, Nguyen Son Hai², Luc Nguyen Tuyen³

1 Department of Cell Biology, Faculty of Biology, University of Hanoi, Vietnam. -2 Department of Entomology, Institute of malaria, Hanoi, Vietnam. -3 Institute of Malaria, Nha Trang, Vietnam.

Anopheles dirus is considered as primary vector of human malarial parasites in Vietnam and neighbouring countries. As other vectors of human malaria they belong to complex species which difficult to identify by classical morphology. Studies on the amount of constitutive heterochromatin in mitotic karyotypes have proven useful for separating closely related species of oriental *Anopheles*.

Cytological examination of F1 larval mitotic chromosomes from a total 179 families of *An. dirus* species A from southern Vietnam population have revealed polymorphism in the sex chromosomes with respect to the amount of constitutive heterochromatin they contain.

Five variations including three forms of X and two forms of Y chromosomes have been identified in wild population samples.

23-165

IMPACT OF AN INSECT GROWTH REGULATOR AND BIOLOGICAL INSECTICIDES ON THE LONGEVITY OF THE ENTOMOPATHOGENIC NEMATODE *STEINERNEMA CARPOCAPSAE* IN MANURE

J. Chirico

Department of Parasitology, National Veterinary Institute, Uppsala, Sweden

An infective Swedish strain of *Steinernema carpocapsae* (Rhabditida: Steinernematidae) failed to control the common housefly, *Musca domestica* (Diptera: Muscidae), in cattle production premises. A series of experiments to investigate the tolerance of the nematode to matters related to animal production premises was carried out. The longevity of the nematode when exposed to manure from cattle as well as swine was assessed. Additionally, the tolerance of the nematode to an insect growth regulator (IGR) (diflubensuron) and two commercial formulations of *Bacillus thuringiensis*, var. *israelensis* and H-14, respectively, was assessed. Animal faeces severely affected the nematodes' longevity over a 72-hour-period. When exposed to cattle faeces 12% of the nematodes survived, while exposure to swine faeces led to only 5% survival. However, the IGR did not severely affect the nematode as 79% survived. The *B. thuringiensis* formulations were highly lethal to the nematodes already within the first 24 hours. Due to its sensitivity for animal faeces, the investigated strain of *S. carpocapsae* was concluded not to be a candidate biological control agent for use in pest management of houseflies in animal production units.

23-167

SUN SCREEN INSECT REPELLENT FORMULATIONS FOR PROTECTION AGAINST MOSQUITOES

Raj K. Gupta, T.A. Klein, R.A. Wirtz, E.E. Wylie

Department of Entomology, Division of Communicable Diseases and Immunology, Walter Reed Army Institute of Research, Washington, DC, USA.

Often the insect repellents reduce the efficacy of sun screens whereas sun screens reduce the longevity of protection of insect repellents when used separately. Sustained-release sun screen repellent formulations with three different delivery mechanisms containing 20% or 30% diethylmethylbenzamide (deet) were evaluated in the laboratory, using volunteers, for repellency against the mosquitoes *Aedes aegypti* (Linn) and *Anopheles stephensi* Liston. The sun protection factor (SPF) in the above formulations varied from 15 to 30 SPF.

The combined sun screen insect repellent formulations provided extended repellency against mosquitoes. This study showed that the repellency was not directly related to the deet concentration in the various formulations and there was no difference in longevity of protection provided by the formulations containing 20% or 30% deet.

23-166

EXPERIMENTAL INDUCTION OF SUMMER MASTITIS BY BACTERIA-EXPOSED *HYDROTAEA IRRITANS*

J. Chirico, P. Jonsson¹, S. Kjellberg² & G. Thomas³.

Department of Parasitology, National Veterinary Institute, Uppsala, Sweden - 1 Department of Veterinary Microbiology, Section of Clinical Bacteriology, Swedish University of Agricultural Sciences, Uppsala, Sweden - 2 Mastitis laboratory, National Veterinary Institute, Uppsala, Sweden - 3 Central Veterinary Institute, Department of Immunology, Lelystad, The Netherlands

Up to now, evidence of the role of *Hydrotaea irritans* to transmit the causative bacteria of summer mastitis, an acute suppurative infection in the udders of heifers and dry cows, has been circumstantial. The vector role of the fly was investigated by experimental infections of recipient heifers exposed to *H. irritans* fed with summer mastitis pathogens. Flies with verified bacterial containment were exposed to teats of eight heifers. Two teats of each animal were subjected to lesions before fly exposure. Two heifers developed summer mastitis in the quarters where teats had been scarified. The bacteria species isolated from these quarters corresponded to those that had previously been fed to the flies. Additionally, some of the pathogens were recovered from fly-exposed quarters without clinical sign of summer mastitis.

In the present study it is, for the first time, demonstrated that *H. irritans* is capable to transmit summer mastitis pathogens and cause clinical summer mastitis on recipient cattle. Lesions on the teat orifice may be a predisposing factor to develop the disease by fly transmission of relevant pathogens. Still, this mode of transmission is probably only one of many for the disease.

23-168

GLOBAL CLIMATE CHANGE: A RESEARCH CHALLENGE FOR APPLIED ENTOMOLOGY, WITH SPECIAL REFERENCE TO MEDICAL AND VETERINARY ENTOMOLOGY

R. Slooff, Ph.D.

Office of Global and Integrated Environmental Health, World Health Organization, 1211 Geneva 27, Switzerland

A Task Group on behalf of WHO, WMO and UNEP, working closely with Working Group II of the Intergovernmental Panel on Climate Change (IPCC), has recently revealed overwhelming evidence of climate-induced triggers in the emergence, re-emergence and resurgence of several infectious human diseases. Many of these diseases depend on insect vectors. Unstable and stable malaria, and dengue disease, now appearing at higher than ever altitudes in tropical mountain areas represent typical examples.

Global climate change forms part of a wider spectrum of human-induced environmental changes, several of which affect population dynamics of insects and disease reservoir species. Ecosystems to be most severely stressed by climate change include coastal zones, large marine ecosystems, agro-ecosystems and forests. Therefore, applied entomologists in the medical, veterinary, agricultural and forestry sectors should join current interdisciplinary impact assessment and monitoring efforts in order to help improve modelling skills, increase forecasting precision and to assist in the design of adaptive responses.

23-169**INITIAL STUDIES TO MAP THE WHITE GENE IN *GLOSSINA MORSITANS SUBMORSITANS* USING RAPD'S****A.S. Robinson, R.H. Gooding¹**FAO/IAEA Agriculture and Biotechnology Laboratory, A-2444
Seibersdorf, Austria - 1 CW405A, Biological Sciences Centre,
University of Alberta, Edmonton, Alberta T6G 2E9, Canada

Very few genetic markers have been characterized in tsetse flies principally because of the difficulty in rearing this species coupled with the low number of progeny per female. A female tsetse will larviposit about eight 3rd instar larvae in her lifetime. The use of DNA polymorphisms generated by PCR will enable DNA from valuable pedigrees to be screened repeatedly to identify molecular markers. As a first step in this approach it was decided to try to map RAPD markers which co-segregate with a white gene in *Glossina morsitans submorsitans*. RAPD markers have also been used to examine geographical variation between populations of *G. austeni*.

The white gene in *Glossina m. submorsitans* is X-linked and a series of pedigrees was set up in which the segregation of this gene could be followed through to the F2 generation. DNA was extracted from thoraces from individuals in the P, F1 and F2 generations. The DNA was resuspended in 60 microlitres of buffer to enable up to 60 assays to be carried out per individual. From one hundred 10mer oligonucleotide primers (UBC RAPD Set 100/1) checked for their ability to amplify DNA from *G. m. submorsitans*, 66 gave reproducible results with a varying number of bands being produced for the different primers.

Initial results of the pedigree analysis identified several primers which produced bands showing segregation with white. These will be confirmed and the analysis extended to include all 66 primers.

Entomology for the Third Millennium - Critical Issues

24-002

QUANTIFICATION OF RISK FOR QUARANTINE SYSTEMS USING COMBINED COMMODITY INFESTATION AND TREATMENT EFFICACY ESTIMATES.

Robert L. Mangan

Crop Quality and Fruit Insects Research, Subtropical Agricultural Research Laboratory, USDA-ARS, 2301 S. International Blvd., Weslaco, TX 78596

Several approaches to determining the risk of pest introduction have been proposed based on rates of infestation of commercial commodities. Rare infestation of the commodities because of non-host status or low pest populations may justify eliminating the requirement for postharvest quarantine treatments or reducing the severity of treatments. The "probit 9" (99.9968% mortality) was proposed in 1939 by USDA entomologists based on treatments for fruit flies. The probit 9 requirement has a questionable mathematical basis and frequently is not obtainable without unacceptable damage to many commodities. Recently techniques to calculate the conditions required ensure a given level of security so as not to exceed a maximum pest limit have been proposed. We examined the risk of pest introduction for the Mexican fruit fly *Anastrepha ludens* Loew for a series host fruits and fruit production regions of Mexico. Proportions of fruit infested and numbers of insects per infested fruit were recorded for commercially important citrus and mango and for native hosts. Then the required treatment efficacy was calculated to allow less than a mating pair of Mexican fruit flies per commercial shipment. In commercial orchards when fruit fly management programs controlled pests, the probit 9 requirement was found to be slightly excessive (99.984% mortality = probit 8.86 would have been sufficient). In cases with no fruit fly control, infestation rates would require treatments far in excess of the probit 9 level (>99.9997% mortality = probit 9.55). These calculations indicate that the currently required treatment efficacy provides security against introduction of a reproductive pair of flies only in fruit production areas that are managed to control fruit flies. The current management systems do not, in general, warrant reduction in treatment efficacy requirements.

24-001

DEVELOPMENT OF A STATISTICAL APPROACH FOR COMPARING THE EFFICACY OF AREA FREEDOM, NON-HOST STATUS AND DISINFESTATION TREATMENTS AS "TREATMENTS" AGAINST FRUIT FLIES (DIPTERA: TEPHRITIDAE)

E. R. Frampton, C. M. Frampton¹

Ministry of Agriculture, Lincoln, New Zealand - 1 Centre for Computing and Biometrics, Lincoln University, New Zealand

The essence of maintaining quarantine security is to minimise the probability of the introduction of a quarantine pest to an acceptable level, in some cases necessitating the application of quarantine treatments. The current methods for ensuring quarantine security against fruit flies that specifically address this probability involve disinfestation treatments based on either a mortality of 99.9968% (probit 9) or modified approaches such as the Maximum Pest Limit. These methods ensure that the probability of an individual or group of individual pests surviving a specific treatment application is at, or lower than, a predefined maximum limit. Other "treatments" which are used to maintain quarantine security, such as area-freedom and non-host status, have not previously been considered within this probabilistic framework. For a disinfestation treatment, the probability of a mating pair surviving can be reasonably estimated. The true error in area-freedom monitoring is the probability of an area not being "free" of a specific pest given that monitoring, which would detect with a certain probability the presence of a specific minimum infestation level, failed to detect the pest. For non-host status assessments, the true error is the probability of a fruit being capable of hosting a pest at minimum infestation levels, given that this capability is not detected. For both area-freedom and non-host status, this minimum infestation level would be set such that if the pest were present then the probability of a mating pair within a consignment does not exceed a specific, maximum level.

24-003

INTERNATIONAL TRADE NEGOTIATIONS

Ralph H. Iwamoto, Jr.

U. S. Department of Agriculture, APHIS, IS, American Embassy, Tokyo, Japan

Negotiations of agricultural issues between two countries who are trading partners should be based upon good science. The need for restrictions or special conditions on exporting products must be supported by biologically sound reasons. If exports of agricultural products are denied because of physical and/or cosmetic characteristics on the cartons, for example, the United States considers this a trade barrier. Several incidents involved U.S. products which were stopped because the labels on the export cartons were curved instead of straight or 2 mm too big or too small.

A more serious phytosanitary issue is the rejection and/or treatment of agricultural exports caused by a policy of "zero tolerance" in reference to finding cosmopolitan or common insects and organisms in arriving shipments. This has led to the question of whether this should be referred to the World Trade Organization when the shipment of a commodity, such as lettuce, has a rejection rate as high as 40-50%

These are problems which lead to trade barrier concerns. International trade negotiations are not only done at the tables of a formal bilateral meeting between two countries, but can and should be negotiated during on-going discussions by the representative in-country. There are a number of effective ways for conducting this.

24-004

IRRADIATION: A NEW CHALLENGE TO INTERNATIONAL TRADE IN FRUITS AND VEGETABLES

Paisan Loaharanu

Food Preservation Section, Joint FAO/IAEA Division of Nuclear Techniques in Food and Agriculture, A-1400 Vienna, Austria

Global trade liberalization in food and agricultural commodities is in effect following the Uruguay rounds of the GATT. Irradiation provides a new challenge to the trade in fresh fruits and vegetables by overcoming quarantine barriers against insect pests, especially fruit flies. This challenge is met through harmonized data on the effectiveness of a small radiation dose (150 Gy minimum) to provide quarantine security against major fruit fly species regardless of host commodities. These data were developed by a research programme of the Joint FAO/IAEA Division and evaluated by international experts appointed by the International Consultative Group on Food Irradiation established under the aegis of FAO, IAEA, and WHO. An international consensus on the acceptance of irradiation as a quarantine treatment was reached by regional plant protection organizations (NAPPO, EPPO, APPPC, COSEVE, OIRSA) which operate within the framework of the International Plant Protection Convention. Following the announcement of the USDA's position to accept irradiation as a quarantine treatment of fresh fruits against major fruit flies regardless of host commodities, a regulation to this effect is expected during 1996 which would open the US market to irradiated fruits, properly treated for quarantine purposes for the first time. The final challenge on the acceptance of irradiated fruits rests with the consumer. Limited commercial-scale marketing of irradiated food conducted in several countries in general and irradiated fruits in the USA in particular, has demonstrated that consumers would be prepared to accept irradiated food once they receive proper information. Thus, irradiation could expand the horizon in trade in fresh fruits and vegetables while keeping the spread of insect pests in check.

24-006

DISINFESTATION OF PESTS ON CUT FLOWERS WITH GAS MIXTURES OF METHYL BROMIDE, PHOSPHINE, AND CARBON DIOXIDE

Fusao Kawakami, H. soma, T. Tsutsumi¹, T. Yuge¹, M. Yamamoto¹

Chemical and Physical Control Laboratory, Research Division, Yokohama Plant Protection Station, Yokohama, Japan - ¹ Research and Development Center, Teijin Chemicals, Ltd., Mihara, Hiroshima, Japan

Each stage of eight species of arthropod pests, *Tetranychus kanzawi*, *T. urticae*, *Thrips palmi*, *Trialeurodes vaporariorum*, *Myzus persicae*, *Aphis gossypii*, *Planococcus kraunhiae*, and *Plutella xylostella*, on chrysanthemum and orchid was fumigated with gas mixtures of methyl bromide (10g/m³), phosphine (3g/m³), and carbon dioxide (5%) for 3, 4, and 6 hours at 15 and 20C. *T. kanzawi* egg was the most resistant stage and was killed completely at doses of 13g/m³ of methyl bromide, 3g/m³ of phosphine and 5% carbon dioxide with 40% (v/v) loading at 15C for 4 hours and 20C for 3 hours. Thirteen percent of the initial dose of methyl bromide was adsorbed by the cut flowers and packing materials, while no phosphine adsorption was observed. Carbon dioxide concentration increased due to respiration of the cut flowers. No injury was observed to six cultivars of chrysanthemum and four cultivars of orchid fumigated at 15C for 4 hours. A slight injury was confirmed on both cut flowers when fumigated at 20C for 3 hours, followed by storage at 15C or above. The injury, however, could be acceptable to commercial trade. Carbon dioxide in the methyl bromide-phosphine mixture is useful to prevent ignition of the phosphine and reduce concentrations of methyl bromide needed which will result in less damage to the flowers.

24-005

THE SYSTEMS APPROACH TO QUARANTINE SECURITY

Aldo Malavasi

Department of Biology, University of Sao Paulo, Sao Paulo, Brazil

Quarantine treatments against fruit and vegetable-infesting pests employed today usually consist of some component, such as heat, cold, or fumigation, which may damage the commodity being treated. The equipment required to apply this treatment and the trained personnel to run it are added expenses to the marketing of fresh commodities. In recent years many commodities have been reported as possessing varying levels of resistance to quarantined pests. The use of plant hormones, such as gibberellic acid, has been shown to reduce the susceptibility of fruits to fruit fly attack. Packing house procedures designed to preserve shelf life often reduce the risk of pest infestation. In situations where sufficient biological and ecological information about the pest-commodity system is available it may be possible to use this knowledge to achieve quarantine security. This method is commonly referred to as the systems approach. The systems approach integrates biological, physical, and operational factors that can affect the incidence, viability, and reproductive potential of a pest into a series of procedures which together provide quarantine security. Some working examples of this technique are grapefruits in Florida, apples from the northwestern US, papayas from parts of Costa Rica and Brazil, avocados from Mexico, and nectarines from California. These successes illustrate a very promising methodology which should expand worldwide during the next millennium.

24-007

THERMOSENSITIVITY IN IMMATURE STAGES OF QUEENSLAND FRUIT FLY, *BACTROCEA TRYONI* (FROGGATT) (DIPTERA: TEPHRITIDAE)

M. S. Osman, N. W. Heather, B. Cribb

Department of Entomology, University of Queensland, St. Lucia, Australia

Immature stages of Queensland fruit fly comprising initially early and mature eggs, were subjected to four preconditioning temperatures (between 30-40C) for one to six hours prior to challenge with a lethal temperature of 46C at a time duration necessary to achieve 50% mortality. At the early egg stage (2 hours old), eggs acclimated at 30, 35, and 37C showed lower, but statistically nonsignificant, percentage mortality than the control group. When eggs were acclimated at 40C, the control showed significantly lower mortality. For the mature egg stage (26 hours old), similar trends occurred for acclimation at 30, 35, and 37C, but greater differences were seen between the acclimated and control, especially for the latter two temperatures. Within the 35 and 37C acclimation group, significant differences in mortality were consistently observed as the duration of acclimation was prolonged. At 40C the mortality of the acclimated group was lower than the control group for the first two hours of treatment, and the trend was reversed until the sixth and final hour of acclimation. Responses of early and mature eggs were, thus, different when subjected to similar acclimation and challenge temperatures. Variations may be due to the differences in 1) stage of egg development, 2) duration of exposure, and 3) acclimation temperature. The implications of each of these factors are discussed.

24-008**HIGH-TEMPERATURE CONTROLLED ATMOSPHERES FOR POST-HARVEST DISINFESTATION OF TEMPERATE ARTHROPODS**Diana C. Whiting

The Horticulture and Food Research Institute of New Zealand, Ltd, Mt. Albert Research Centre, Auckland, New Zealand

Controlled atmospheres and heat are separately under intensive investigation as non-chemical postharvest disinfestation treatments against temperate arthropods of quarantine importance found on fresh fruit. Combining these two accepted technologies results in novel treatments capable of comparable pest kill with reduced doses of each components. In addition, high temperature-controlled atmosphere treatment combinations provide greater scope for modification to a) control pest complexes on the same host fruit, and/or b) recognise the specific treatment tolerances of different host fruit types. Further treatment flexibility lies in manipulation of the application protocol of such treatments.

Recent examples from the high-temperature controlled atmosphere research programme to disinfest New Zealand export apples, kiwifruit and stonefruit of Lepidoptera, Hemiptera, and Acari will be discussed, and possible avenues for future treatment combinations with other pest control strategies applied either before or after harvest will be highlighted.

24-009**NOVEL TECHNOLOGIES FOR QUARANTINE TREATMENTS**Guy J. Hallman

U.S. Department of Agriculture, Agricultural Research Service, Weslaco, Texas, USA

Several events are increasing the need for new types of quarantine treatments. Ethylene dibromide was lost as a fumigant a decade ago, and methyl bromide may be lost by the end of this century or shortly thereafter. More commodities host to more pests are being transported to more countries than ever before. Improvements are sought in some treatments which have been developed to replace fumigants. The cold treatment is lengthy (two weeks or more) and causes damage to some commodities on which it is currently being used. Hot water immersion of mangoes often damages mangoes. New methods of quarantine treatment are being studied. Fruit coatings and waxes have been shown to kill surface and interior quarantine pests. Coating combines well with other fruit fly quarantine treatments, such as heat and insecticide dip. Coatings by themselves may yield considerable levels of fruit fly mortality, thus, being useful to the systems approach. Ohmic heating shows promise as a quarantine treatment. An electrical current is passed through fruit and resistance causes the fruit to heat. Fruit can be heated to temperatures sufficient to kill fruit fly immatures fairly uniformly in a matter of a few minutes. Other treatments, such as microwave heating and high pressure, are being examined in new ways which may show promise as quarantine treatments in the third millennium.

24-010**DEVELOPMENT OF QUARANTINE STRATEGIES IN LIEU OF TREATMENT--THE CASE OF THE WALNUT HUSK FLY AND STONE FRUITS EXPORTED FROM CALIFORNIA**Victoria Y. Yokoyama and Gina T. Miller

U.S. Department of Agriculture, Agricultural Research Service, Fresno, California, USA

The walnut husk fly, *Rhagoletis completa* Cresson (Diptera: Tephritidae), has been considered a pest of regulatory concern by certain countries that import stone fruits from California. Research showed that the risk of accidental introductions of the fruit fly into foreign countries was minimal based on the establishment of a pest-free period between the beginning of stone fruit harvest and July 1. The pest is not prevalent in its normal host, walnut orchards, during this period in the San Joaquin Valley of California where the highest production of stone fruit in the world occurs. The pest-free period was verified in 1990-1994 through an extensive trapping program in walnuts in five counties (Merced, Madera, Fresno, Tulare, and Kern) in the San Joaquin Valley. The pest-free period was further supported by research that showed that peaches and nectarines were not good hosts and unlikely to be infested and that plums were not a walnut husk fly host. Another quarantine strategy, low temperature fruit storage, was found to minimize risk for accidental introductions of the pest into foreign countries. Although a methyl bromide fumigation was developed as a quarantine treatment to control walnut husk fly in peaches, industry preferred the development and use of alternative control strategies. Acceptance of the research resulted in regulatory agreements that allow export of peaches, nectarines, and plums from five counties in California and supports a multi-million dollar global export market.

24-011**THE WORLD WIDE WEB AND AGRICULTURE - WHY AND WHO**

R. E. Stinner and George Schaefer

North Carolina State University, Department of Entomology
Raleigh, NC 27695-7634

Cornell University, Department of Entomology, NYS Experiment Station, Box 462, Geneva, NY 14456

The World Wide Web has exploded as a major source of agricultural information. This paper will examine the organizations active in promoting the Web for agriculture, a brief history, and the benefits (and shortcomings) of information dissemination on the World Wide Web.

24-012

SUSTAINABLE CROP PROTECTION INFORMATION FROM THE INTERNATIONAL AGRICULTURAL RESEARCH CENTERS

R.H. Markham, J.S. Yaninek, P. Neuenschwander

International Institute of Tropical Agriculture. Plant Health Management Division, Cotonou, Republic of Benin.

Global Strategies for Electronic Communication of IPM Knowledge Bases. Organizers: Drs. G. Schaefer (CICP) and R. Stinner (CIPM)

Research related to sustainable crop protection forms a very significant part of the work of the International Agricultural Research Centers (IARCs) of the Consultative Group for International Agricultural Research (CGIAR). However, this work has not realized its full potential in contributing to the worldwide implementation of integrated pest management (IPM) for lack of an effective mechanism to coordinate these activities and make their results widely available. To address this need, the CGIAR System-wide Programme for IPM was launched at the beginning of 1996. An important component of the System-wide Programme will be to provide a common electronic access point to the wealth of relevant information already available and continuously being generated. In this initiative, the System-wide Programme will work closely with partners in information technology outside the CGIAR system to ensure the maximum possible compatibility and synergism with their efforts. Within this broader context, the IARCs can play a constructive role in helping to ensure that the information technology initiative as a whole is fully responsive to the needs of their IPM partners in the national agricultural research systems of developing countries and can assist directly in making relevant information fully accessible to these partners.

24-014

THE CROP PROTECTION COMPENDIUM - REGIONAL APPLICATION AND GLOBAL STRATEGY

Peter Scott, Charles Schotman, Anne Sweetmore, Stephen Rudgard, Bin-Cheng Zhang

CAB International, Wallingford OX10 8DE, UK
Fax: +44 1491 833508. E-mail: p.scott@cabi.org

The Crop Protection Compendium is an encyclopaedic database resource for use on PCs, designed to provide access to information on all aspects of pests and their integrated management from a single point and in a user-friendly format. A version for South-East Asia, to be published in 1996, contains data sheets on 1000 pests, diseases and weeds of economic significance to the region, together with information about their natural enemies and host crops. For each species, biological and agricultural data are supplemented by text descriptions, illustrations, distribution maps, abstracts of the literature, taxonomic information, accounts of control, and diagnostic systems, all connected through relational links and with points of access to external databases.

A special focus is placed on IPM. The Compendium presents balanced information about the full range of control measures for each pest, including plant quarantine, cultural control, genetic resistance, biological control, and the appropriate use of pesticides. A bibliographic database of the international literature of IPM is included, with special emphasis on South-East Asia.

The Crop Protection Compendium will be published on CD-ROM. An extensive survey of user needs indicates that it will be keenly used by a wide range of pest management specialists, extension staff, quarantine officers, plant breeders, university teachers and students, crop managers, and policy makers. Users will be able to record their own in-context notes electronically and will be invited to submit these to the developers, to be screened for possible use in keeping the Compendium accurate and up to date.

The Crop Protection Compendium for South-East Asia is expected to become an influential standard resource in and beyond the region, widely used in IPM projects. It will be followed in 1998 by a version with global coverage. This will provide a strong basis for a global information system for IPM.

24-013

TED RADCLIFFE'S GOPHER STATE IPM SITE: IPM TEXTBOOK ON THE WORLD WIDE WEB

E. B. Radcliffe¹ W. D. Hutchison¹ and G. A. Schaefer²

¹Department of Entomology, University of Minnesota, St. Paul, MN, USA and

²Consortium for International Crop Protection, Cornell University, Geneva, NY, USA.

We have launched development of an IPM textbook, Ted Radcliffe's Gopher State IPM Site (URL: < <http://www.ent.agri.umn.edu/academics/classes/ipm/ipmsite.htm> >), on the World Wide Web (Internet). This project is an initiative of the University of Minnesota and co-sponsored by the Consortium for International Crop Protection (CICP) and the National IPM Network (NIPMN).

As of 1 January 1996, more than 100 US and internationally prominent entomologists have agreed to contribute chapters on various aspects of IPM. We intend to expand coverage to include all pest management disciplines. We invite contributions (3,500-5,000 words, with 5-7 color photographs and 5-10 key references) from IPM specialists around the world. There is no limit on the number of chapters we can post and different perspectives on the same topic are desired. We will initiate a system of peer review of contributions and to leave material posted on the server for 2 years. Chapters can be updated or completely revised whenever the authors wish.

Our purpose in constructing this site is to provide: 1) a venue for easily maintaining and up-dating "state of the art" information from the world's leading experts on all aspects of IPM, 2) a resource economically deliverable anywhere in the world that can be freely downloaded and used by students, teachers, and IPM practitioners, 3) a forum for the international presentation of practical information and theory on IPM, 4) links to the vast and rapidly growing IPM resources available on the Internet including photographs, and decision-support software.

24-015

THE NATIONAL IPM NETWORK - ONE ANSWER TO THE INFORMATION GLUT ON THE INTERNET

R. E. Stinner

Center for Integrated Pest Management, 840 Method Rd., Unit I, Raleigh, NC 27607

The National IPM Network (NIPMN) in the United States was established as a grass-roots effort to provide electronic dissemination of pest management information to diverse audiences. NIPMN includes a national server and four regional servers linked with many state servers.

24-016

IPMNET, A RESPONSE TO THE CRITICAL NEED FOR INTERNATIONAL IPM INFORMATION/COMMUNICATIONG. Schaefers

Consortium for International Crop Protection. New York State Agricultural Experiment Station, Geneva, New York, 14456, U.S.A.

Global Strategies for Electronic Communication of IPM Knowledge Bases
Organizers: Drs. G. Schaefers (CICP) and R. Stinner (CIPM)

Launched on the internet by the Consortium for International Crop Protection in 1993, IPMnet was designed in response to the need for improved crop protection strategies of less developed countries. It was launched on the Web in 1995 (<http://ipmwww.ncsu.edu/cicp/cicp.html>). It is currently operating with a search mechanism, registration database, various information databases, an interactive bulletin board, and the monthly IPMnet News. Plans are underway to develop a more global approach through partnerships with other international IPM systems. The Consortium is convinced that its emphasis on electronic communication can serve as a cost effective, primary mechanism for the cooperation and collaboration that is needed to increase the rate of development and adoption of effective IPM in developing nations.

24-018

IPM WORKING FOR DEVELOPMENT: INTERNATIONAL COOPERATION THROUGH THE INTERNETC. Addison/M. J. Iles

European IPM Working Group and the International IPM Forum, NRI, Central Avenue, Chatham Maritime, Kent, ME4 4TB, UK.

Global support for information exchange and regional and local initiatives for the promotion and implementation of integrated pest management.
Secretary: Mr Malcolm Iles (NRI).

The European IPM Working Group server started in 1994 has recently developed a WWW site (<http://www.nri.org/ecart.htm>) serving the European Research Community with database information on Project activities in IPM and a guide to Institutional and Professional resources. This forms part of a wider initiative supported by the International IPM Forum to make newsletters and publications freely available through the Internet and disseminate IPM information in disk CD Rom and hard copy form to those without Internet access.

24-017

AFRICALINK AND OTHER INITIATIVES OF THE U.S. AGENCY FOR INTERNATIONAL DEVELOPMENT (USAID) TO FACILITATE IPM INFORMATION NETWORKING IN AFRICA AND WORLDWIDE
W. I. Knausenberger¹, J. Cochrane¹, R. Hedlund², W. Ravlin³ and George A. Schaefers⁴

1 Division of Productive Sector Growth and Environment, Africa Bureau, USAID/AFR/SD/PSGE, Washington, DC USA - 2 Office of Agriculture and Food Security, Global Bureau, USAID/G/EG/AFS, Washington, D.C USA - 3 Department of Entomology, Virginia Polytechnic Inst. & State Univ., Blacksburg, VA USA - 4 Consortium for International Crop Protection, NYSAES - Cornell University, Geneva, NY USA

USAID is engaged in a number of activities to facilitate access to the Internet and other electronic communications media for its colleagues and partners. Worldwide, public access to electronic mail connectivity is least developed in Africa: some 15 countries lack even the most basic access. A specific initiative to address this need is AfricaLink, in which the focus is on the end users of technical information, such as for crop protection. Within the context of each country's existing infrastructural and regulatory environment, AfricaLink implements simple strategies to help end users obtain electronic mail access as quickly as possible. As a general strategy, AfricaLink encourages networks to obtain electronic mail access through a local service provider.

USAID's IPM Collaborative Research Support Project is working with AfricaLink to connect scientists, NGOs and other users and developers of IPM information in African countries. It is also establishing networking connections among IPM researchers and practitioners and colleagues in the Caribbean, Central and South America, Eastern Europe, and Southeast Asia, with the immediate goal of promoting more efficient collaboration with U.S.-based colleagues. This process is being facilitated through cooperation between the U.S. National IPM Network and the internationally-oriented IPM Net of the Consortium for International Crop Protection. Case studies will demonstrate how a two-fold purpose is being promoted, to (a) transfer appropriate information technology and strategies, while (b) strengthening indigenous crop protection capacities in developing countries.

24-019

A CLASS TO ENABLE TEACHERS TO USE INSECTS TO FACILITATE LEARNING BY ELEMENTARY STUDENTS.A.C. York

Department of Entomology, Purdue University, West Lafayette, IN USA

In the Entomology Department at Purdue University I have created a one-credit, two-hour per week laboratory course designed to teach future and current teachers how to use insects in the classroom as learning tools. Because we believe that most children have an inherent interest in and curiosity about insects, they are an ideal classroom learning aid. They are effective as tools for teaching not just science and math, but social studies, language arts, human hygiene, and management of insect pests. The course uses a group of insects readily available to most teachers and easily and conveniently maintained as classroom "pets." The students in this course become extremely familiar with this group of insects and feel comfortable handling, raising, and using them to achieve desired educational objectives. Moreover, should a teacher decide to teach a unit about insects, the material learned in this class provide everything needed to easily do so. In addition to achieving its goals, this class has achieved additional success in that students completing this class frequently enroll in additional classes in entomology: introductory entomology, insect behavior, apiculture, or spider biology.

24-020

"GETTING A BUZZ FROM INSECTS" - AN AUSTRALIAN PROGRAM FOR ENCOURAGING INSECT EDUCATIONAL ACTIVITIES IN SCHOOLS.

G.B.Monteith & H.A.Janetzki

Queensland Museum, Brisbane, Queensland, Australia.

Insects have much to offer school curricula. They are attractive, diverse, versatile, easy to breed, short lived, available everywhere and usually free. School children come to public museums for advice and assistance in undertaking school projects with insects. In fact they often come in such large numbers that staff can't cope. We found that a major reason they come is because their teachers have very poor knowledge about insects and the ways to use them in the classroom.

To try to achieve the dual result of reducing school children demands on staff time and improving teacher skills with insects, we devised an intensive 3-hour hands-on workshop for the teachers themselves. To break down the powerful cultural inhibition against touching "creepy crawlies" we gave them the opportunity to handle about 25 species of living insects, ranging from mealworms to locusts, caterpillars, phasmids and giant burrowing cockroaches. In an atmosphere of fun we led them through the evolutionary success story of Insects and on to catching, preserving, breeding, modelling and experimenting with them. We stressed the improvisation of apparatus (nets, pinning boards, cages) from spare materials so that teachers could themselves put into practice every activity we taught them. They received a resource kit of printed information and other ideas.

The workshop proved immensely popular among teachers. Sessions at the Museum in Brisbane were booked out when offered. Later by gaining sponsorship assistance from commercial traders (a Butterfly House and a retailer of insect apparatus) we were able to tour the workshop around Australia. This tour was linked with separate tours of travelling insect exhibitions. The workshop has now been presented 104 times in 25 centres around Australia and has given insect skills to almost 2,000 teachers.

This workshop program has had a significant effect on the level of insect awareness in Australian schools and provides a simple formula which many other Museums could follow.

24-022

NONTRADITIONAL LEARNING OF ENTOMOLOGY

C. Y. Oseto

Department of Entomology, Purdue University, West Lafayette, IN USA

Entomology and entomologists continue to suffer from an image problem. Many people characterize entomologists as slightly eccentric, a bit weird, and downright strange because of the subject they study. Movies and other media support this stereotype through the dissemination of improper materials. Entomologists need to inform the public of the wonders of entomology and the important role that entomologists play in their everyday lives. While classroom education can help, only a small fraction of people are reached and educated. Young people have an innate fascination for insects and their arthropod relatives but adults, through their own negative attitudes toward insects, overtly or subliminally discourage further exploration into entomology. Entomologists have the opportunity to educate a wide audience through non-traditional educational. Bug Bowl, presented by the Department of Entomology at Purdue University, has been a spectacular success reaching 7,000 people over a two-day period. Other successful, non-traditional programs are presented.

24-021

INSECTS FOR CHILDREN

D. L. Kulhavy¹, P. C. Johnson²

College of Forestry, Stephen F. Austin State University, Nacogdoches, TX USA - 1 Department of Natural Resources, University of New Hampshire, Durham, NH USA

Children have a natural affinity for the diverse and intriguing world of insects. We have developed and participated in programs that bring the wonderment of entomology to children in both classrooms and in natural settings. Examples of programs include: 1) Life in A Pinecone; this program was developed using Berlese funnels to collect insects from pine cones after seed release. New species of insects collected included species of Psocoptera (barklice). An educational module was developed for collecting insects from pine cones; 2) The Monarch Butterfly's Marvelous Migration; the ecology and migration of the monarch butterfly, *Daneus plexippus* L., were demonstrated in both in-class presentations in New Hampshire and Texas; and in a poster sent between schools. The poster was later expanded and titled "Butterflies 'n Beetles;" the final poster on insects was 45 cm wide and 1000 m long. It was displayed in the Smithsonian Institution Museum of Natural History in Washington, D.C. The project has been expanded across the United States; 3) Outreach Programs Using Insects in the Classroom; as part of regional and national meetings and local volunteer efforts, insects and insect displays are brought into classrooms and to exhibit areas. One activity included coordination of Insect Expo '94 through the Entomological Society of America national meeting in Dallas, TX. Over 50 presenters and 3500 youth interacted with insects displays, presentations and insect lore. These three examples are ideas for entomologists using insects in their presentations.

24-023

PREPARATION OF ENTOMOLOGY STUDENTS FOR A CAREER IN THE AGRICHEMICAL INDUSTRY

F.D. Tenne

Agricultural Products Research Division
American Cyanamid Company, Princeton, NJ USA

Major agrichemical companies operate global businesses. There is a need for well trained entomologists to enter into these companies. Students need to acquire and demonstrate competency in scientific disciplines, communications, and social skills. Excellence in these collective skills significantly influence and enhance the success potential of students as employees.

Initiatives by American Cyanamid to attract and develop students as potential employees is an ongoing process. University involvement in working collaboratively with industry to prepare students will ensure students entrance and career contributions as employees in the agrichemical industry.

24-024

TECHNIQUES AND STRATEGIES FOR TEACHING
ENTOMOLOGY TO LARGE CLASSES
F.T. Turpin (West Lafayette-United States)

ABSTRACT NOT RECEIVED

24-025

ENTOMOLOGY AND PLANT PROTECTION EDUCATION
IN SOUTH AMERICA

Jorge E. Frana

Instituto Nacional de Tecnologia Agropecuaria, Santa Fe,
Argentina

South America embodies fourteen countries with different environments ranging from plains to high mountains, and climates from tropical to polar. How to approach youth education with such insect diversity? Yet there are two big concerns: preservation of the habitat and food production for local and foreign markets. With both objectives in mind, most countries follow the traditional way of teaching basic entomology through biology departments and applied entomology through agronomy departments. A discussion is provided of entomology and plant protection education at the undergraduate and graduate levels in these countries.

24-026

ENTOMOLOGICAL EDUCATION: CAN WE REALLY TRAIN
STUDENTS TO BE HOLISTIC?
R.G. McKinlay, D. Wyllie (Edinburgh-United Kingdom)

ABSTRACT NOT RECEIVED

24-027

COMPUTER BASED IDENTIFICATION, TRAINING AND
SUPPORT IN ENTOMOLOGY

M.P. Zalucki

Cooperative Research Centre for Tropical Pest Management and
Department of Entomology, The University of Queensland, Brisbane,
Australia.

Making knowledge accessible to all inquiring minds will be the hall mark of the next century. The lack of ready access to libraries of 'scholarly works', and the mysterious jargon in which such works are often written, has in part constrained communication even within disciplines. The advent of personal computers, linked by improved telecommunications and software, is ushering in a new age of open learning. To realise the potential these technological developments offer a discipline such as entomology requires a new approach to packaging and presenting information. In a 'hands on' workshop, we present a number of sophisticated yet user friendly software packages being developed to take entomology to a much wider audience. The software packages illustrate this new approach to problems ranging from the simple presentation of 'facts' about particular insects, to interactive identifications keys; from training students in diagnosing pest problems, to developing complex models of insect life cycles, and from analysing the distribution of a species and its potential for spread, to running simulation of insect migration over the world wide web. Specific software packages that will be demonstrated at the workshop include:

BUGMATCH - a decision support system for growers and consultants
LUCID - an interactive taxonomic key and builder
DIAGNOSIS - an interactive game which teaches diagnostic skills
GENSECT - a generic population model and builder
CLIMEX - for predicting species distribution
GENSIM - a spatial model to predict movement of migratory pests

This symposium and workshop will interest all entomologist concerned with communicating information about insects; be they teachers wanting to excite students about their science, or researchers needing to make results readily digestible to the public and even fellow scientists.

24-028

AN EXPERT SYSTEM FOR CLASSICAL BIOLOGICAL CONTROL

M.A. Golosova, F.N. Semevski¹, L.C. Thompson²

The Moscow Forestry Institute, Moscow, Russia - 1 Institute of Global Climate and Ecology, Moscow, Russia - 2 University of Arkansas, Monticello, Arkansas, USA.

This system forecasts the outcomes of classical biological control activities. The system includes a database, three groups of population and economic models, commentary, and a tutorial. The forecasts are based on analysis of historical data, experience in classical biological control, and the modern theory of population dynamics. One can select from three groups of models: First, population dynamics of the target species (pest) in its new area of residence. Second, a model representing how natural enemies would suppress the pest in its new land. Third, a model describing interactions between the natural control agent and the target species. An economic module calculates a return on investment in the biological control effort. The system also includes an adaptive feature when supplied with new information. The system may be useful for both teaching and applying biological control. The system is written in Professional BASIC, and uses 1.2 megabytes of disk memory.

24-029

A MONITORING OF SOME INSECT IN NORTH CAUCASUS BY DINT OF REMOTE SENSING METHODS AND FORECASTING EXPERT SYSTEMS

M.I. Saulich

All-Russian Institute of Plant Protection, Saint-Petersburgh, Russia

In pursuing these aims the methodical approaches have been developed: remote sensing phytosanitary diagnostics and forecasting based on expert computer systems. Remote sensing methods are oriented to application of visual observations from helicopters and large-scale air-photography from light aircrafts for discovery of microfocuses with breeding of such species as *Lema melanopus* (L.), *Zabrus tenebrioides* (Göese), *Loxostege sticticalis* (L.), larvae of *Agriotes* sp..

As diagnostic indicators, parameters of lots of vegetables damaged by insect-phytophages are used in grain, industrial and fodder crops. It is being developed models for going from damage estimations to insect densities on fields.

Expert computer systems are created using LOTUS PLUS "shell", allowing to a large degree to automate the process of base knowledge development for short-, long-term and long-standing forecastings of population dynamics of above mentioned insect species and some others.

In the end, a combination of forecasting and remote sensing diagnostics leads to a significant reduction of plant protect measures and pollution environment with pesticides, application of soft measures of struggle with consideration for environment protection interest.

A general scheme of monitoring of main phytophage distribution is illustrated for grain, industrial and fodder crops.

24-030

CABIKEY - A NEW MULTIPLE ENTRY KEY SYSTEM FOR IBM COMPATIBLE PERSONAL COMPUTERS

I. M. White

International Institute of Entomology, 56 Queen's Gate, London SW7 9R, UK.

CABIKEY (Computer Aided Biological Identification System) is CAB International's software package for interactive identification. CABIKEY is a multiple entry key, i.e. it works directly from a database of coded taxonomic descriptions, rather than through a hierarchy of ordered questions. CABIKEY was initially developed for the MS-DOS operating system and the DOS version of the software has now been used for a beetle family key (available from CABI since late 1994) and a key to European thrips pests (available very soon). Other current CABIKEY projects include mosquito genera, a group of fruit flies, thrips from other regions and two termite applications; many of these projects are joint with the Natural History Museum. A Windows version of CABIKEY is now being developed, including a special "developers" version that will allow the creation and editing of new keys. The Windows version of CABIKEY allows the user to run in a simplified mode, an advanced mode, or to choose characters (questions) almost at will. The advanced mode lists characters both by recommendation and then by a separation "score" based on the number of paired combinations of remaining taxa each character separates. The simplified mode presents characters in sequence following the recommended and score sorted lists (which remain hidden in this mode). Characters are presented as pictures with supporting text and help files. Each taxon can be allocated text, pictures and a distribution map, plus a video or sound clip. Facilities are also provided to list a tabulated comparison of two taxa and to place any two or more pictures together for comparison. The developers version will also allow import and export of DELTA and spreadsheet compatible ASCII files, the export of HENNIG files, and provide its own spreadsheet-like editing interface for the data.

24-031

A HYPERTEXT ON PREDATORS OF DIASPIDID (HOMOPTERA, DIASPIDOIDEA)

F. Porcelli*, L. De Marzo**

* Istituto di Entomologia Agraria - Università di Bari - Italy.

** Dipartimento di Biologia, Difesa e Biotecnologie agro-forestali Università della Basilicata - Potenza - Italy.

Diaspidid predators belong to lots of different taxonomical groups and are currently diffused or dispersed to colonize new zoogeographical regions. That's why it's difficult to discriminate useful insects for a field technician.

A hypertext is presented, which allows identification of diaspidid predators from whole the world; it gives the following information for each species:

- 1) taxonomic position;
- 2) distribution;
- 3) bionomics;
- 4) diaspidid hosts;
- 5) diaspidid host plant;
- 6) iconography

Information are searchable either by predators name or diaspidid species or diaspidid host plants or geographical region or macroscopical characters.

24-032

APPLICATION OF MICROCOMPUTER IN AGRICULTURAL INSECT IDENTIFICATION

Xiao-qi Wang, Hong-qiang Feng, Xiu-yun Ding, Huang Feng

Department of Plant Protection, Shenyang Agricultural University, Shenyang, 110161, P.R. China

The software for identification system of agricultural insect was made by FOXbase+. This software identifies agricultural insects basing on combination of morphological characters and injury characters, which makes it easy to be applied and popularized, as well to identify correctly. On screen design, user-friendly interface, novel pictures and optional menus make very easy to be learned, i.e. you can operate it by pressing simply function keys to draw a conclusion. This system contains information of 33 orders of insects, 240 families and 44 species of agricultural insects, in which there are: 1. classification of insects, 2. identification of soil insect, 3. identification of insect pests of rice, 4. identification of insect pests of cereals. The software, with function of study, was available for veteran and recruit working for plant protection. e.g. In identification of underground insect pests, there are several items as follows: (1) classification of soil insect, (2) identification of grubs, (3) identification of wire worms, (4) identification of mole crickets, (5) identification of cutworms, (6) identification of Tenebrionidae, (7) identification of veevils. If you are given an soil insect, belonging to the group of grubs as you know, you can identify it on the level of species using item (2), on the other hand you can also classify it firstly into a certain group of pests using item (1), without knowing which group it belongs to and then continue to identify it on the level of species. In the procedure of identification, the system also has the function of searching backward, thus it can correct errors in time and draw a conclusion quickly.

24-034

STUDY ON ESTABLISHMENT RISK OF CODLING MOTH, *CYDIA POMONELLA* (L.), IN CHINA BY USING GEOGRAPHICAL INFORMATION SYSTEM

LIN Wei, ZHANG Cong-zhong

Plant Quarantine Institute, Ministry of Agriculture, Beijing, P.R. CHINA.

The method on application of Geographical Information System (GIS) on Pest Risk Analysis (PRA) was developed. Data on selected variables that influence the geographic distribution of codling moth *Cydia pomonella* (L.) were assembled and entered into a computerized geographical information system to study relationship between climatic factors and geographical distribution of codling moth. The studies showed geographic distribution of this pest in latitude might be determined by temperature and temperature sum and geographic distribution in longitude had close relationship with rainfall from June to September. Depending on above variables, the preliminary forecasting results indicated the potential suitable establishment area located mainly in the west of China and the part of northeast of China. The potential unsuitable establishment area located mainly in the south of China and the part of east of China.

24-033

COMPUTERIZED EXPERT SYSTEM FOR IDENTIFICATION OF THE FAMILIES OF CHALCIDOIDEA (HYMENOPTERA)

A. Sharkov

Department of Entomology, Museum of Biological Diversity, The Ohio State University, Columbus, Ohio, USA.

Computerized expert systems for taxon identification have many advantages over traditional identification devices, such as dichotomous keys. For the developer, one of the most important feature of such systems is that the addition or exclusion of characters and taxa can be done without the entire modification of the system structure. For the user, the most obvious advantage is the absence of the author-defined order of characters: in every step of the identification the user can select any of the available characters and skip the ones that cannot be observed or are uncertain. With the increasing availability and affordability of the computer technology, especially of notebook computers, it is very likely that expert systems will soon replace traditional methods of taxa identification.

The presented computerized identification system was developed using the Delta and Intkey for Windows software packages, and allows the identification of the families of the superfamily Chalcidoidea - a large and important group of parasitic Hymenoptera.

24-035

TAKEING CHIGGER (TROMBICULIDAE: ACARI) MORPHOLOGIC AND TAXONOMIC STUDIES INTO THE TWENTY-FIRST CENTURY.

W. A. Brown & M. L. Goff

Acarology Laboratory, Department of Entomology, University of Hawaii, Honolulu, Hawaii, USA

It has been proposed that studies on the ultrastructure of members of the family Trombiculidae of the sub-class Acari be carried out. The objective being to enhance our knowledge of morphological characteristics of general and specialized structures of this acarine group. With enhanced clarity of morphology the specialized structures could be more accurately evaluated and taxonomic relationships better assessed.

The proposed studies would encompass the comparison of phase contrast photomicrographs, illustrations and measurements with scanning electron microscope photomicrographs, establishment of morphologic character and character states, and utilization of classical chigger taxonomy and cladistic analysis to determine new taxa or synonymies.

24-036

EXPORT QUARANTINE STATUS OF *ATHERIGONA ORIENTALIS* (MUSCIDAE DIPTERA) ON FRESH HORTICULTURAL COMMODITIES FROM AUSTRALIA.

S. Schlack, N.W. Heather, E. Hassan, University of Queensland
Gatton College, Lawes Australia.

Market access of Australian tomatoes and cucurbits to New Zealand has been impeded by restrictions relating to the presence of eggs of *Atherigona orientalis* Schiner on fruit. Trials were conducted on the incidental effects of fruit fly treatments with the insecticidal dips with dimethoate and fenthion. Natural mortality was high supporting those literature reports which categorised the species as saprophage. Overall, the combination of incidental effects of fruit fly treatments with insecticides, together with normal mortality gave an assurance that egg numbers would be <99.5%. When viability of eggs present at pre-export inspection is corrected for this mortality, most produce grown is in accordance with good agricultural practice set out in the Bilateral Quarantine Agreement between the two countries and can meet the New Zealand permissible tolerance of <1 infected fruit in 200. The uncertainty over whether the pest is saprophagous or phytophagous is discussed in terms of the results recorded.

24-037

MORTALITY RESPONSE OF TWO COOK ISLAND FRUIT FLY (DIPTERA: TEPHRIIDAE) SPECIES TO HOT WATER IMMERSION

B.C. Waddell, G.K. Clarc, J.H. Maindonald
The Horticulture and Food Research Institute of New Zealand Limited,
Mount Albert Research Centre, Auckland, New Zealand

Changes in the quarantine treatment technology used for disinfecting Cook Island fruit were necessitated by the lowering of the maximum allowable residue of ethylene dibromide detected in fumigated papaya destined for the New Zealand market. Postharvest fumigation was replaced by heat treatment which has itself been widely investigated as an alternative to chemical treatments particularly for tropical fruits. As a first step in developing this postharvest heat treatment it was necessary to identify the relative heat tolerance of the various life stages of the various pest species that may potentially be found on or in the fruit at the time of harvest. Once identified, this most tolerant species/life stage was included in all subsequent research to develop the treatment parameters that will be effective in killing species of quarantine concern without damaging the fruit.

In this study the mortality responses of two species of fruit fly *Bactrocera melanotus* (Coquillett) and *B. xanthodes* (Broun) to heat treatments were investigated. Temperatures in the range 43-48°C were used to test the response of eggs (<6 h, >24 h), first instar, second instar, and third instars (young, mid, old) to hot water immersion. The most heat tolerant life stage was >24 h eggs followed by first instars, third instars (of all ages), and finally <6 h eggs which were least tolerant. Species comparisons showed that *B. melanotus* eggs were more heat tolerant than *B. xanthodes* eggs while the reverse was true for larvae. Overall *B. melanotus* >24 h eggs were significantly more heat tolerant than all other life stages of both species tested.

24-038

THERMAL DEATH KINETICS IN EGGS AND THIRD INSTAR OF THREE SPECIES OF FRUIT FLIES (DIPTERA: TEPHRIIDAE)

DUARTE, A.L.¹; JANG, E.B.²; MALAVASI, A.¹

¹ Dept. Biologia, Inst. Biociências, USP, São Paulo, Brazil; ² ARS/USDA,
Hilo, Hawaii, USA

The kinetics of thermal death and death rate curves for eggs and third instar larvae of Mediterranean fruit fly, *Ceratitis capitata* (Wiedemann); the South American fruit fly, *Anastrepha fraterculus* (Wiedemann) and the West Indian fruit fly, *A. obliqua* (Macquart) were determined at temperatures between 43 and 48°C and for times of up to 160 min using a hot water-immersion technique. Both eggs and larvae of all three species showed mortality that was directly related to the severity of treatment and time of exposure. The curves of survivorship exhibited nonlogarithmic death that were characterized by an initial lag in mortality followed by an increasing death rate with time at a given temperature. Eggs were more resistant to heat than larvae at a given temperature. *A. fraterculus* eggs and larvae appeared more sensitive to heat than those of either of *C. capitata* and *A. obliqua*. This information may be useful in determining suitable commodities attacked by these insects.

Italian Entomology

25-001

LIST OF THE ENTOMOLOGICAL COLLECTIONS HELD IN ITALIAN PUBLIC INSTITUTIONS

R. Poggi¹, C. Conci²

1 Museo Civico di Storia Naturale "G. Doria", Genova, Italy - 2 Museo Civico di Storia Naturale, Milano, Italy

A list of the public entomological collections stored in Italy is presented and briefly commented.

This is the first attempt to gather in one paper the data on Italian collections (which now are scattered in the literature or quite unpublished), with the aim to provide a helpful guide for the location of old and recent entomological materials.

A series of information is given for all the collectors and for those travellers who enriched the Italian Institutions with significant series of specimens. The private collections of living people are not quoted, except for the parts which already became of public property.

25-002

ICONOGRAPHY OF ITALIAN ENTOMOLOGISTS, WITH ESSENTIAL BIOGRAPHICAL DATA

C. Conci¹, R. Poggi²

1 Museo Civico di Storia Naturale, Milano, Italy -

2 Museo Civico di Storia Naturale "G. Doria", Genova, Italy.

The work will be a homage to the persons who in Italy worked in Entomology. It is reported the iconography of about 400 no-living persons who published papers, mostly taxonomic or faunistic, on pure or applied Entomology. It also includes some persons who made only collections which are preserved in public Institutes, and also a few foreign Entomologists who made important collections in Italy.

For comments and complements to Iconography, the essential biographical data of the figured, and also of many not figured, persons are reported. Altogether, about 600 names are commented.

The bibliography is limited to the principal one subsequent to the work of Conci (1975).
